WANTED LOCUM TENENS: Multi specialty group desires pediatrician for one year. Salary open. Contact: Northwestern Clinic, Crookston, Minnesota.

PRACTICE FOR SALE: North Central Minnesota. General practitioner grossing $60,000 a year. Fully equipped eight room clinic with X-ray. New 32-bed hospital nearby. Reasonable and/or terms. Write: MINNESOTA MEDICINE — 306; 496 Lowry Medical Arts Building; St. Paul 55102.

LAKE SHORE for sale. East shore Blue Lake, 8 miles north of Park Rapids. Crystal clear water; excellent beach. Four of 5 biggest walleyes of 1964 Fuller Contest caught here. Norway, White and Jack pine and birch. Six miles to golf course; 8 miles to Val Chatel ski lift. Duck and deer hunting. Have more than I need for privacy; will sell 200 feet $6,000. H. C. Rice, M.D.; Moorhead, Minnesota.

IF YOU ARE a G.P. grossing under $70,000 will you consider buying or leasing my clinic in Twin Cities. Practice thrown in. Will work with doctor until established. Write: MINNESOTA MEDICINE — 313, 496 Lowry Medical Arts Building, St. Paul 55102.

They say best men are molded out of faults. And, for the most, become much better for being a little bad. — Shakespeare

Hygroton®
brand of chlorthalidone

the long-acting diuretic

Indications: Many types of edema involving retention of salt and water.
Contraindications: Hypersensitivity and most cases of severe renal or hepatic disease.
Precautions: Reduce dosage of concomitant antihypertensive agents by at least one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take special care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.
Side Effects: Agranulocytosis, constipation, dizziness, dysuria, headache, hyperglycemia, hyperuricemia, impotence, leukopenia, muscle cramps, nausea, postural hypotension, purpura, thrombocytopenia, transient myopia, urticaria, vomiting and weakness.
Average Dosage: One tablet (100 mg.) daily with breakfast.
Availability: Tablets of 100 mg. in bottles of 100 and 1000.
For full details, see the complete prescribing information.

Hygroton®
brand of chlorthalidone

In terms of sodium excretion, 2 tablets of Hygroton brand of chlorthalidone, are significantly more potent than 4 tablets of chlorothiazide, and also more potent—though not significantly—than 4 tablets of hydrochlorothiazide.* Thus, tablet for tablet, you can expect more from Hygroton, brand of chlorthalidone. Especially since it acts for up to 72 hours. You can prescribe fewer tablets at wider intervals than with any other diuretic.

Distress for Allergic Patients

Benadryl®

(diphenhydramine hydrochloride)

PARKE-DAVIS

To Combat Symptoms of Weed-Pollen Allergy

This time-tested agent provides two actions that effectively combat symptoms of seasonal allergy: *Antihistaminic*—relieves sneezing, nasal congestion, itching, and lacrimation. *Antispasmodic*—relieves bronchial and gastrointestinal spasm. **Precautions:** Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this product. Hypnotics, sedatives, or tranquilizers, if used with BENADRYL, should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENADRYL. **Side Effects:** Side reactions, commonly associated with antihistaminic therapy and generally mild, may affect the nervous, gastrointestinal, and cardiovascular systems. Most frequent reactions are drowsiness, dizziness, dryness of the mouth, nausea, and nervousness. BENADRYL is available in Kapseals® of 50 mg. and Capsules of 25 mg. diphenhydramine hydrochloride. The pink capsule with the white band is a trademark of Parke, Davis & Company.

LACTINEX®

TABLETS & GRANULES

to help restore and stabilize the intestinal flora

for fever blisters and canker sores of herpetic origin

LACTINEX—a viable culture containing both *Lactobacillus acidophilus* and *L. bulgaricus*—was first introduced to help restore the flora of the intestinal tract in infants and adults.[1, 2, 3, 4]

Further clinical work showed LACTINEX to be successful in the treatment of fever blisters and canker sores of herpetic origin.[4, 5, 6, 7]

No untoward side effects have been reported in 12 years of clinical use.

Literature on indications and dosage available on request.

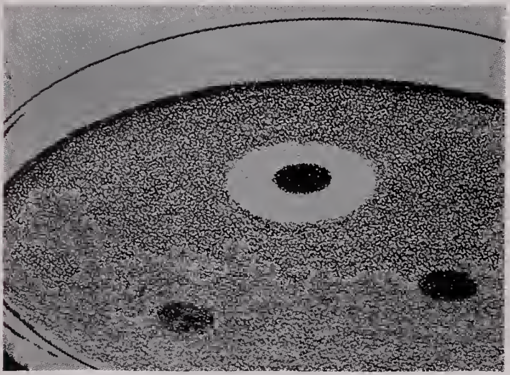
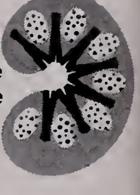
stop proteus, too!





treat the source
with optimal dosage

NegGram®

Brand of
nalidixic acid

Stop most gram-negative urinary infections.

Before they can develop into pyelonephritis, pyonephrosis or some other potentially life-threatening urinary condition. With NegGram, a specific urinary antibacterial. Clinical reports and extensive patient use show that in adults two 500 mg. NegGram Caplets® orally four times a day will control most urinary infections. Quickly...effectively...with minimal side effects. **Gram-negative urinary infection—cystitis, pyelitis, pyelonephritis, prostatitis, urethritis? Start first with NegGram ..."a good 'starting' drug."**[1] NegGram "...treatment may be first choice in potentially curable gram negative bacterial urinary infections."[2]

Indications: Urinary tract infections caused by gram-negative and some gram-positive organisms.

Side effects: Mainly mild, transient gastrointestinal disturbances; in occasional instances, drowsiness, fatigue, pruritus, rash, urticaria, mild eosinophilia, reversible subjective visual disturbances (overbrightness of lights, change in visual color perception, difficulty in focusing, decrease in visual acuity and double vision), and reversible photosensitivity reactions. Marked overdosage, coupled with certain predisposing factors, has produced brief convulsions in a few patients.

Precautions: As with all new drugs, blood and liver function tests are advisable during prolonged treatment. **Pending further experience, like most chemotherapeutic agents, this drug should not be given in the first trimester of pregnancy. It must be used cautiously in patients with liver disease or severe impairment of kidney function.** Because photosensitivity reactions have occurred in a small number of cases, patients should be cautioned to avoid unnecessary exposure to direct sunlight while receiving NegGram, and if a reaction occurs, therapy should be discontinued. The dosage recommended for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Bacterial resistance may develop.

When testing the urine for glucose in patients receiving NegGram, Clinistix® Reagent Strips or Tes-Tape® should be used since other reagents give a false-positive reaction.

Dosage: Adults: Four Gm. daily by mouth (2 Caplets® of 500 mg. four times daily) for one to two weeks. Thereafter, if prolonged treatment is indicated, the dosage may be reduced to two Gm. daily. Children may be given approximately ***25 mg. per pound*** **of body weight per day, administered in divided doses. The dosage recommended above for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Until further experience is gained, infants under 1 month should not be treated with the drug.**

How supplied: Buff-colored, scored Caplets® of **500 mg. for adults,** conveniently available in bottles of 56 (sufficient for one full week of therapy) and in bottles of 1,000. **250 mg. for children,** available in bottles of 56 and 1,000.

GENERAL INFORMATION

Authors

Manuscripts for consideration in Minnesota Medicine should be addressed to Office of Publication, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102. Papers should be typed double spaced on white paper with a wide margin. The first page should list the title, the name of the author (or authors), degree, and any institutional or other credits. Pages should be numbered consecutively. Tables should be typed and numbered and should have a brief descriptive caption.

Bibliographical references should be limited to twelve and should be typed in conformity to the method used by the Index Medicus. They should be numbered consecutively in the order in which they first appear in the text. Book references should give the name of the author, title, edition number, publisher, and the year.

Illustrations (photographs, tables, and graphs) should be submitted on separate sheets of paper and not combined in the text. Instructions for combining photographs are acceptable.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

On Stelazine® brand of trifluoperazine
she's calm and alert

When a tranquilizer is needed, 'Stelazine' can regulate the level of anxiety so that the patient is unlikely to overreact to stress but is not tranquilized into psychic inertia. Patients on 'Stelazine' often experience a sense of mental alertness and, because they feel so much better, are more interested in their normal activities.

Contraindicated in comatose or greatly depressed states due to CNS depressants and in cases of existing blood dyscrasias, bone marrow depression and pre-existing liver damage. *Principal side effects,* usually dose-related, may include mild skin reaction, dry mouth, insomnia, fatigue, drowsiness, dizziness and neuromuscular (extrapyramidal) reactions. Muscular weakness, anorexia, rash, lactation and blurred vision may also be observed. Blood dyscrasias and jaundice have been extremely rare. Use with caution in patients with impaired cardiovascular systems.

Before prescribing, see SK&F product Prescribing Information.

President's Letter

There has just come across my desk a report of the First National Conference for Professional Nurses and Physicians, sponsored by the American Nursing Association and the American Medical Association. This conference, which was held in 1964, was devoted to major problems in the relationships of our two professions. There was much discussion about the independent and divergent paths which professional nursing has taken when appraised in the light of the traditional concept of the nurse as held by most physicians. If one conclusion may be cited, it was the need jointly to discuss, understand, and evaluate our separate roles in the good care of the patient.

In most hospitals today the physician encounters a rather formally organized nursing service. There is a graduate nurse who is a supervisor or leader of a group which may include graduates on floor duty, licensed practical nurses, nurses' aides, diploma or three-year students, and perhaps college degree students. Each is usually identified by a distinctive uniform, often in a pastel color, and each has or should have a well understood function in patient care, assigned according to training and ability. When there is a student program, direction most likely comes from an administration which is not primarily concerned with patient care but with the learning experience of the student, and in many student programs actual nursing service is minimal. This is hard for a physician to understand, and it is also an additional item in the cost to the patient if the cost of an educational program is included in the daily charge which the hospital makes. Lessened student hours of patient care and the shortened work week of graduate nurses have contributed to a shortage of personnel actually engaged in nursing care which is of vital concern to all.

In contrast to the organized nursing staff responsible to the hospital administration for the most efficient care possible, the physicians of the staff are often highly individualistic with many variable concepts of what should be done for their patients. It is understandable that conflicts of opinion should arise. Probably few of us would really be willing to turn back the clock. We realize that in our busy hospital practice the well educated graduate nurse of today, trained with the knowledge of medical science to understand the increasingly complex procedures of modern medicine and to direct a nursing group, is an essential part of the medical team. But the nursing profession and the hospital administration must not lose sight of the individual physician's intense concern for every facet of the patient's care. None of us, physician, nurse and administrator, should be too busy to find time to discuss and understand the others' problem and to plan cooperatively so that each knows the role of the other.

I will close this letter with one practical suggestion. When things go wrong do not castigate the first uniformed female you see but seek out the person in charge and find a quiet place to present your problems. If there are interns and residents they will profit by your example and your patients or the relatives in the hall will not become unduly alarmed or perhaps amused.

JMStickney M.D.

J. M. Stickney, M.D.

security checkpoint

Even raw materials of the highest quality are not above suspicion. That's why we screen them through this "security sieve." It separates foreign elements from all incoming material intended for granulation. Here's how it works: The screen vibrates over a tub at the rate of 1,000 to 3,000 times a minute and sifts the material. Anything larger than the specified particles is left behind. The sieve is engineered by an action called "annular rotation" so that all particles will ultimately come in contact with the screen surface. Security screening is just one aspect of an elaborate program at Eli Lilly and Company to insure the highest quality in our finished products.

The Clinician Views Potassium Deficit

W. D. SNIVELY, JR., M.D.*
R. L. WESTERMAN, M.D.**
Evansville, Indiana

THE ELECTROLYTE potassium has great clinical importance, yet contrasts and paradoxes lace its story. Although essential for life and deeply involved in that vital wellspring, the cell, potassium can be the deadliest of poisons. Resembling its close relative sodium in chemical nature, it strikingly opposes sodium in most of its physiologic actions. Although the body contrives to keep the cellular concentration of potassium at a high level — in defiance of known physical-chemical laws — it fails to conserve potassium, even when the patient is dying of a deficit.

As Fenn[1] pointed out, "A normal adult has enough potassium in his body to kill 100 people if it were injected into their blood, yet if he got no potassium in his diet he would soon be paralyzed and die." Should the concentration of plasma potassium increase to more than three or four times normal, the heart will stop beating. If as little as 6 per cent of cellular potassium could escape quickly into the extracellular fluid, one would quickly die. Although the usual human intake of potassium is about 3 grams (approximately 77 mEq.) a day, one could become gravely ill from the potassium ingested at a single meal if the kidneys and body cells did not keep watch over the rising level of plasma potassium derived from absorbed food.

Incidence of Potassium Deficit

The studies of Surawicz and others[14] revealed the high incidence of potassium deficit in many hospital patients. During the period from October 1, 1954, to April 30, 1955, they determined the plasma potassium level in 1,497 adult male and 1,289 adult female inpatients of the Philadelphia General Hospital. Potassium concentrations below 3.5 mEq./L were found in 273 men (18

per cent) and in 284 women (22 per cent). Berger[34] used negative potassium balance and decreased plasma chloride with elevated bicarbonate as criteria for the diagnosis of potassium deficit, in surveying the entire patient population of a small general hospital. Twenty per cent (24 of 120) exhibited potassium deficit. In emphasizing the high incidence of potassium deficit, Berger[42] stated that it can occur in pediatric, medical, and surgical patients.

When Read and others[15] administered chlorothiazide to patients with ascites resulting from liver cirrhosis, they found an increase in the urinary output of potassium. All patients who did not receive potassium supplements developed hypokalemia.* Bartels and others[17] administered chlorothiazide to 65 patients with hypertension; 28 patients (43 per cent) showed a drop in potassium level to 3.5 mEq./L or below. Relman and Schwartz[11] emphasized the frequency of the nephropathy of potassium depletion.

Physiologic Considerations

As Nicholson and Herring[6] pointed out, potassium should be viewed as an element that exists in the fluids of the body in concentrations that are reasonably constant for each body fluid. Of the adult's 3,000 mEq. of potassium, only 50 to 70 mEq. are normally contained in the extracellular fluid.

The exact minimal daily requirement for man is not known. On a normal, average diet, deficiency of potassium does not occur since this element is found in practically all foodstuffs. Dietary intakes of potassium in normal adults have been found to range from a low of 51 mEq. to a high of 125 mEq. per 24 hours. Normally, about 80 to 90 per cent of ingested potassium is excreted in the urine, with the remainder in the stools and sweat. Fasting adults without any sodium intake soon compensate and excrete little sodium after the second day of such a fast. In contrast, if an adult is fasting or on a diet adequate in calories but potassium free, urinary loss of potassium continues in the amount of 40 to 50 mEq. daily. The daily loss is even more important in children, who have a greater potassium exchange than adults.[29]

Luetscher and Curtis[8] early emphasized the importance of aldosterone in the regulation of sodium and potassium balance. One mechanism for the conservation of sodium involves the production of additional aldosterone. While conserving sodium and water, aldosterone increases the excretion of potassium. In addition to the aldosterone mechanism for potassium excretion, there is another kidney mechanism that helps regulate potassium: the distal convoluted tubules of the kidney secrete potassium into the urine whenever the potassium concentration becomes too high in the extracellular fluid. This effect presumably is brought about by the direct stimulation of high potassium concentration on the tubular epithelial cells.[38]

Excretion of potassium via the urine follows a fairly fixed pattern.[37,40] The diurnal rhythms of excretion of potassium, sodium, and chloride appear to be under the control of subcortical parts of the brain, such as the hypothalamus.[51]

While the consensus appears to be that conservation of potassium is almost nonexistent, Berman[43] maintained that potassium conservation does occur, at least to a limited extent.

Etiology

Cannon[7] emphasized that potassium deficit may be found in a great variety of clinical conditions. We have summarized the usual antecedents of potassium deficit as follows:

I. *Conditions Causing Excessive Loss of Potassium from the Body*
A. Medical Therapy
thiazide-type diuretics[15-19,31-33,41,53]
adrenal steroids
infusion of solutions of saline or dextrose not containing potassium
treatment of diabetic acidosis
excessive laxation[6,20]
repeated enemas[10]
mercurial diuretics, alone or with ammonium chloride
ion exchange resins
therapeutic low sodium diet
absorption of fludrocortisone[24]
disulfiram alcohol reaction
administration of radioactive iodine

---

*See Test Your Word Score Page 763.

- B. Surgical Therapy
  - ileostomy
  - colostomy
  - ureterosigmoidostomy[22]
  - resection of large portion of large or small intestines
  - gastric or intestinal tubal drainage
- C. Metabolic Diseases
  - periodic familial paralysis
  - excessive production of aldosterone, as in nephrosis, cirrhosis, or malignant hypertension
  - stress syndrome (whether physical, as in chronic illness, or psychological, as in severe emotional depression)
  - diabetes insipidus
  - uncontrolled diabetes mellitus
  - aminoaciduria
  - alkalosis
  - Cushing's syndrome
  - massive breakdown of body protein
- D. Diseases of the Intestinal Tract
  - ulcerative colitis
  - diarrhea, with or without vomiting
  - fistula of the small or large intestine
- E. Trauma
  - massive destruction of tissue
  - severe burns
  - wound exudation
  - crush syndrome
- F. Renal Disease
  - chronic nephritis
  - diuretic phase of nephritis

II. *Conditions Involving Increased Utilization of Potassium by the Body*
  - healing phase of burns
  - recovery from diabetic acidosis

III. *Conditions Characterized by Decreased Intake of Potassium*
  - poor nutrition[5,23]
  - nausea
  - anorexia[27]
  - acute alcoholism
  - starvation of disease
  - therapeutic starvation

Sackner and others[31] emphasized that claims that one benzothiadiazine compound causes less potassium depletion than others are meaningless unless endogenous aldosterone secretion, which of itself causes potassium excretion, is considered. Relman[39] emphasized that primary aldosteronism causes recurrent or persistent hypokalemia. Thus the finding of unexplained hypokalemia should alert the clinician to the possibility of primary aldosteronism.

Symptoms and Physical Findings

Probably the most common symptom of potassium deficit is malaise, often expressed as "just not feeling well." Since potassium deficit may be associated with other illnesses, this symptom may not impress either the patient or the physician. Muscular weakness is almost always noted and should lead one to suspect potassium deficit. In chronic potassium deficit, malaise and muscular weakness may persist for many months and be interpreted as being due to emotional instability, neurasthenia, or psychasthenia. Berger[42] has characterized the clinical features as follows:

1. *neuromuscular features,* including weakness, diminished to absent reflexes, confusion, muscles flabby like a half-filled water bottle. The patient lies flat like a cadaver, not rounded.
2. *cardiovascular features,* including weak pulse and faint heart sounds. Later, heart block and falling blood pressure may appear.
3. *gastrointestinal features,* including vomiting and paralytic ileus.
4. *respiratory features,* including shallow respiration.

Nicholson and Herring[6] have emphasized the need for care in distinguishing between hypokalemia and hyperkalemia. Holliday and others[28] emphasized that polydipsia occurs frequently in potassium deficit. Weisberg[29] stated that specific clinical manifestations of themselves are of little help in the early recognition of body potassium deficit.

Pathologic Lesions

When Darrow[12] first described clinical potassium deficit in infantile diarrhea, he was focusing interest on an ailment that had been almost universally fatal. Little or no interest was expressed in the after-effects of potassium deficit. Perkins and others[2] in 1950 focused attention on the possible sequelae of prolonged potassium deficit when they reported the necropsy of a patient with chronic diarrhea, who had shown clinical, laboratory, and electrocardiographic evidence of potassium deficit. The following lesions were found:

Focal myocardial necrosis with cellular infiltration and fibrosis

Focal endocarditis

Pronounced hydropic degeneration of the renal tubules

These lesions, identical to those reported in potassium-deficient animals, have been repeatedly observed after chronic potassium deprivation.[3,4,11,21,22,23,27,28,35,36,42,44]

Newberne[44] found that prolonged potassium deficit causes severe damage in the heart and kidneys of the rat. The pathologic alterations observed in the heart indicate that the primary site of injury is the myocardial fiber. The kidney cortex had dilated tubules, some containing casts. Most of the tubules at the corticomedullary zone and outer medulla were grossly dilated.

Diagnosis

Determination of the plasma potassium can be helpful in diagnosis of potassium deficit if its limitations are understood and if repeated determinations are made. Simultaneous determination of the concentrations of sodium, chloride, and bicarbonate, as well as the packed cell volume, add valuable information useful when aggressive electrolyte repair is planned. The electrocardiograph can help, although in the presence of severe myocardial damage following infarction or digitalis intoxication, the typical picture of potassium deficit may be obscured.

Darrow[12] and, later, Snively and Sweeney[9] placed great emphasis on the usefulness of the clinical history in diagnosing potassium deficit. While Weaver and Burchell[25] maintained that a definite correlation can be established between the electrocardiogram and the serum potassium level at hypokalemic values, a normal electrocardiogram does not exclude hypokalemia. An electrocardiogram fulfilling the usually established criteria for hypokalemia is not pathognomonic of the condition.

Sweeney's[30] simple, yet comprehensive method of diagramming electrolyte deficits and excesses places due emphasis on the partition of potassium and other electrolytes between the cells and the extracellular fluid.

The normal concentrations of potassium within the plasma makes minor variations important.[32] As Berger[34] stated, one requires repeated determinations of the plasma potassium level to diagnose potassium deficit. Urinary excretion of more than 70 mEq. of potassium per 24 hours when the patient is on a normal diet should suggest excessive loss of potassium. An increasing plasma bicarbonate plus a decreasing plasma chloride indicate a developing potassium deficit. In alkalosis, chloride is lost, probably because the potassium in the extracellular fluid is excreted rapidly as potassium chloride. The hypochloremia results in loss of an anion, which can be met only by an increase in the readily available bicarbonate.

As Moyer[19] pointed out, the symptoms of opposed imbalances may neutralize each other. However, such composite pictures are of more theoretical than practical interest.

Laboratory tests especially helpful in the diagnosis of body potassium deficit include the urine pH, urine potassium, plasma potassium, plasma chloride, plasma bicarbonate, and plasma pH. Usually, in a well-de-

Useful Potassium Information

To convert milligrams/potassium to milliequivalents/potassium, multiply milligrams by .0256; thus, 100 mg. potassium equal 2.56 mEq.

Remember:

1. If pH of extracellular fluid decreases, extracellular potassium rises; if pH of extracellular fluid rises, extracellular potassium decreases.
2. If dextrose enters the cells, plasma potassium also enters the cells; the plasma potassium level decreases.
3. Potassium and hydrogen compete for excretion but exchange with sodium in the distal convoluted tubule. Therefore, if plasma potassium goes down, hydrogen may be excreted preferentially.
4. Aldosterone favors conservation of sodium — excretion of potassium.
5. Potassium is primarily cellular; 98 per cent of the body's potassium is within the cells.
6. The plasma potassium level at a given moment is the end product of a variety of factors — only one of which is the body's potassium stores.

veloped deficit of potassium, the urine pH will be alkaline; the urine potassium will be increased over 70 mEq. every 24 hours; the plasma potassium will be decreased; the plasma chloride will be decreased; the plasma bicarbonate will be increased; and the plasma pH will be increased. Information of interest in diagnosis of potassium deficit is presented in Table 3.

Management

Prevention

The physician can frequently anticipate potassium deficit by awareness of the predisposing clinical conditions. Correction of such conditions — for example, diarrhea — stops the potassium loss and makes unnecessary the preventive administration of potassium.

Potassium deficit can be prevented by including adequate potassium in parenteral infusions of electrolytes and dextrose; by avoiding the persistent use of laxatives or enemas; by the prompt correction of vomiting; by the replacement of electrolytes lost through fistulas of the small intestine or colon; by prompt diagnosis and correction of aldosterone-producing tumors of the adrenal cortex; by replacement of electrolytes lost through ileostomy or colostomy or ureterosigmoidostomy; by the careful observation of the patient undergoing severe physical or emotional stress; by the prompt diagnosis and treatment of diabetes insipidus or diabetes mellitus; by the prompt correction of renal disease in which excessive potassium is being lost in the urine; by meticulous attention to the nutrition of sick persons such as those with prolonged nausea, chronic infectious disease, anorexia nervosa, or alcoholism.

In considering administration of potassium for prevention of potassium deficit, one should recall that normally about 80 per cent of the potassium ingested is excreted in the urine, the remainder being excreted in the stools and perspiration. Fasting adults on a diet adequate in calories but potassium-free, lose from 40 to 50 mEq. of potassium each day in the urine. Martz[36] has emphasized the need for administering supplementary potassium for patients receiving thiazide diuretics.

The oral route is the best route for prophylactic administration of potassium. If oral administration is impossible, then administration by nasogastric tube or by rectal infusion should be considered. Potassium can be administered prophylactically either through the use of foods high in potassium or through potassium-containing mineral supplements. In order to obtain the potassium required by ingestion of high-potassium foods, the patient is forced to eat relatively large quantities of these foods, which he may not like, or which may not be readily available. Potassium supplements, on the other hand, are readily available. Various potassium-rich foods are listed in Table 4.

TABLE 4
Potassium Content of Potassium-Rich Foods

	Potassium-Milli-equivalents
Fruits	
Apricots, raw, 2-3 medium	7.06

Brazil Nuts, shelled, 4 medium	2.56
shelled, 1/3 cup	17.15
Instant Coffee, Folgers, 2 gm. dry in 240 cc. water	6.14

For years potassium chloride has been regarded as a satisfactory source of oral potassium, despite the fact that it is relatively irritating to the gastric and intestinal mucosa. Now, serious questions have been raised as to the safety of potassium chloride. Lindhomer[46] reported 20 patients with stenosis and ulcer of the small intestine, which apparently resulted from the ingestion of enteric-coated potassium chloride. Baker and others[49] reported primary nonspecific ulceration and stenosis of the small intestine in 12 patients in one hospital over a 15-month period. Eleven were receiving enteric-coated potassium chloride at the time of the acute illness. In an editorial in the same issue of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,[50] the validity of the findings of Baker and others was corroborated. Use of potassium salts other than the chloride, and especially other than the enteric-coated chloride, appears desirable for prophylaxis. Recent corroboration of the potential hazards of enteric-coated potassium chloride includes articles by Buchan and Houston,[54] Morgenstern and others,[55] and Lawrason and others.[56]

The usual dose for prophylaxis of potassium deficit is 50 mEq. daily, in addition to that contained in a well-balanced diet. A useful rule of thumb suggests that the patient receive a daily quota of potassium equal to his daily urinary excretion plus 10 per cent. Thus, if a patient was found to be excreting 160 mEq. of potassium in the urine each day, the correct total potassium intake for prevention of a deficit would be 176 mEq. daily. If the dietary intake of potassium was estimated at 75 mEq. then one would administer about 100 mEq. of potassium as a supplement.

Correction

Correction of potassium deficit should be carried out by the oral or nasogastric route, if possible.[6,9,13,42] Workers have agreed that potassium, as well as other electrolytes, should not be given parenterally except by the intravenous route, since subcutaneous and intramuscular injection of water and electrolytes present many unjustifiable hazards.[9]

Flear and others,[13] and De Graeff and others[52] emphasized the association of potassium deficit with alkalosis. If the ingestion of chloride in the diet is not sufficient to produce a normal plasma chloride, then ammonium chloride should be given along with the chloride-free potassium salt. Measurements of the plasma chloride and bicarbonate, as well as the potassium, can help the physician determine whether it is necessary to give ammonium chloride or not.

Winsor[26] stated that the use of potassium salts in the treatment of digitalis toxicity should be undertaken with caution, while emphasizing that digitalis intoxication can appear for the first time when hypokalemia develops and that the correction of hypokalemia may decrease the signs and symptoms of digitalis intoxication.

Any treatment regimen for potassium should include not only correction of the deficit, but administration of amounts adequate for daily maintenance. If the patient has been vomiting, one should replace such amounts of potassium and chloride as are lost in the vomitus. Should any question exist as to the safety of administration of potassium, the physician can proceed as long as repeated plasma levels are normal. If the level is not rising or if the individual has normal renal function and is excreting about 2 ml. of urine per minute (120 ml. of urine per hour), the chances of producing potassium accumulation are so small as to be negligible.

The possible value of administration of potassium to restore myocardial response to a failing cardiac pacemaker has been discussed pro and con in the recent literature.[47,48]

Summary

Deficit of potassium is a more prevalent clinical condition than commonly appreciated. It depends in part on the body's strange failure to conserve potassium efficiently. It can be caused by excessive loss of potassium from the body, increased utilization, or decreased intake. Early, the symptoms and physical findings of potassium deficit are vague and confusing. Later, they become all too clear, and include widespread weakness of intestinal, cardiac, and skeletal muscle. Pathologic changes in the heart and kidneys have been observed following prolonged potassium deficit. Diagnosis of potassium deficit is based on the clinical history, symptoms, and physical findings. A systematic and comprehensive analysis of the recent history is required, particularly for early diagnosis. The physician can frequently anticipate potassium deficit by a thorough knowledge of how potassium deficits develop. In many clinical states, administration of supplementary potassium will be needed if one is to prevent the accumulation of a deficit. Management of potassium deficit calls for the administration of potassium, preferably by the oral route. Oral administration of potassium is best carried out by the use of a chloride-free salt of potassium. If additional chloride is required because of the presence of a chloride deficit (as in hypokalemic alkalosis) chloride can be administered via dietary sources or as a salt of chloride.

The world is full of willing people; some willing to work, the rest willing to let them. — Robert Frost

Pyelographic Changes

in Decreased Renal Blood Supply*

THE PYELOGRAPHIC changes associated with a decrease in the renal blood supply can be placed in essentially five different categories: 1. Difference in renal size; 2. Normal or no detectable change on routine examination; 3. Difference in opacification in the nephrographic phase or in the pyelographic phase; 4. Nonfunction; 5. Pyelonephritis.

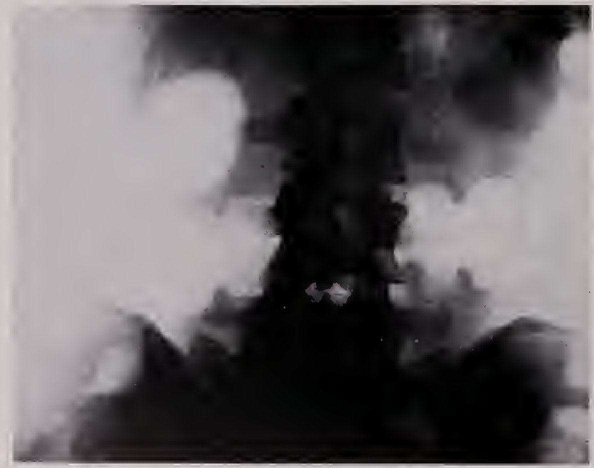

Fig. 1 — Reduced immediate nephrographic effect on the right in a 19-year-old girl with hypertension.

Illustrative Cases

Disparity in the Nephrographic Phase of Excretion

Figure 1 is a film exposed for 30 seconds after injection of routine contrast material in a 19-year-old girl with diastolic hypertension. There was an excellent nephrogram on the left but reduced immediate nephrographic effect on the right.

Disparity in Density at the Pyelographic Phase, Difference in Renal Size, and Pyelonephritis

Figure 2 represents a film taken 26 minutes after injection of the contrast material in the same individual as illustrated in Figure 1. This shows a good concentration of contrast in a normal-size left kidney and reduced concentration in a smaller right kidney, plus changes associated with pyelonephritis. The right kidney was removed and her blood pressure returned to normal.

These four findings which can be isolated findings in individual cases were all demonstrable in this instance.

---

*Read before the Minnesota Radiological Society Meeting, February 29, 1964, Minneapolis, Minnesota.

H. HARRISON EELKEMA, M.D.
St. Paul, Minnesota

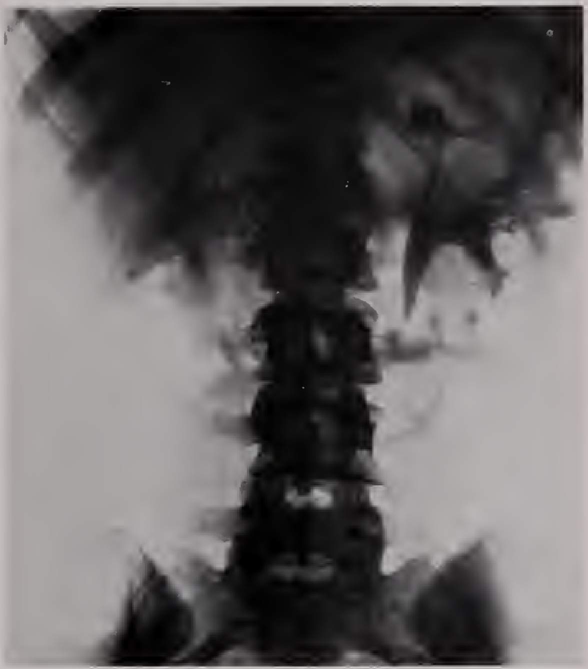

Fig. 2 — Same case as Fig. 1. Film at 26 minutes showing reduced concentration of contrast and smaller right kidney.

Complete Obstruction of the Left Renal Artery

Figure 3 illustrates nonfunction of the left kidney in a 71-year-old man whose presenting complaints were myocardial infarction and high blood pressure. Five months prior to this admission he had had pain in his left flank, followed by three days of bowel trouble. Retrograde examination revealed a normal collecting system, but the angiogram demonstrated complete obstruction of the left renal artery. The left kidney was removed and his blood pressure promptly returned to normal levels and has remained normal.

Stenotic Lesion of the Left Renal Artery

Figure 4 illustrates a normal urogram obtained in a 31-year-old man with diastolic hypertension, heart failure, and marked edema. It was subsequently demonstrated that he had a stenotic lesion in the left renal artery. Left nephrectomy was done when arterial reconstruction failed.

The above cases were selected for illustration from a group of 55 available for review. In over 50 per cent, abnormal findings such as nonfunction, marked variation in size, or excretion, were readily recognized and reported.

Difference in Contrast Density

In 11 cases the urogram was read as normal. These 11 cases were reviewed and classified as to positive or negative on the basis of (1) a difference in density in contrast, and (2) renal size (including circumferential measurements).

Differentiation by Difference in Density

In these 11 cases, differentiation by difference in densities was difficult. Aside from the difficulties in examination itself, such as preparation, state of hydration, technical factors, and presence of complicating medical conditions such as diabetes or heart failure, several other factors can be mentioned. The kidneys are richly supplied with blood and have been likened to an arterial venous fistula as far as oxygen consumption is concerned.

Figure 5 represents diagramatically a 70-kilogram man who has 5 kilos of blood, 7 per cent of his body weight. The middle fig-

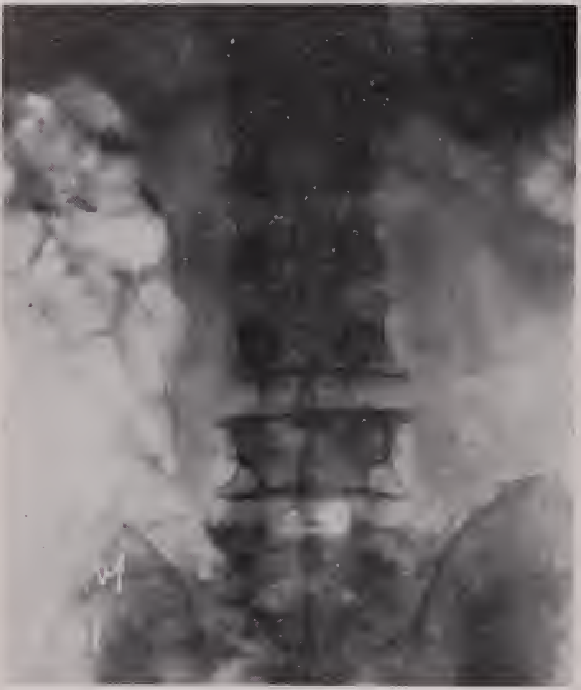

Fig. 3 — Nonfunctioning left kidney in a 71-year-old man subsequently proven to have left renal artery obstruction.

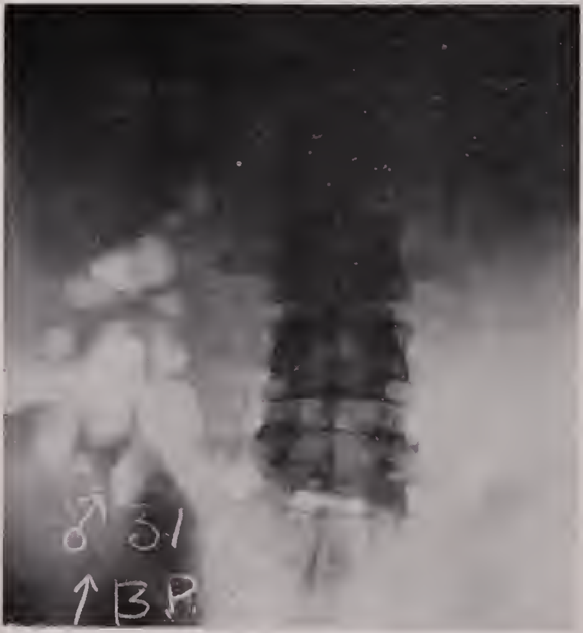

Fig. 4 — Examination considered normal in a 31-year-old man with clinically significant arterial obstruction on the left.

ure represents the renal mass of .3 kilos, 20 per cent of which is blood. The figure on the right represents the resting cardiac output, of which 20 per cent, or 1 liter per minute, profuses the kidneys. Very roughly, this would mean that in the resting phase the blood in the kidneys is changing fifteen times per minute. Even if blood flow to one kidney were reduced 30 to 50 per cent, there would still be a tremendous change of blood per minute through this organ.

Then consider that with contrast media now available we are offering the kidneys 10 grams of iodine, far in excess of what is necessary to do an adequate examination in a well prepared patient. The variability of water absorption with occlusive lesions of the renal artery also adds to the difficulty in evaluation of contrast density. Taking these into account, there appear to be adequate reasons for difficulties in appreciating slight differences in concentration of contrast.

Renal Size

Returning to Figure 5 note that approximately 20 per cent of the weight of the renal mass is blood. There is evidence beginning to appear in the literature that the change we see in length and size of the kidneys is not necessarily an atrophy of the kidney, but a change in the volume of blood and solute that is in the kidney at the time of examination. De Bakey has observed a revascularized kidney even at operation to increase in size. Drs. Kincaid and Utz, in Emmett's book, report that under general anesthesia the larger kidney which is being normally profused will decrease in size and approach the size of the affected kidney. With this in mind the 11 cases were reviewed and measurements in height, width, and circumference of the kidneys were obtained.

To acquire some idea of normal difference in length and circumference, 50 normal cases were reviewed. Measurements were made on films exposed 30 seconds after injection of contrast in which the renal outlines were brightened by the nephrographic effect. Circumferences were obtained by using a map measure. Figure 6 represents the results in these 50 normal tensive patients. Note that in 16 per cent of the cases there was a difference in length of 1 cm. or more. Only 6 per cent showed a circumference difference of 2 cm. or more. Figure 7 represents findings in the 11 "normal" urograms. Using length difference of 1 cm. or more 4 of 11 affected kidneys could be suspected. Using circumference difference of 2 cm. or more the side of the arterial lesion was indicated in 9 of 11 cases.

Discussion

In well over half of a series of 55 cases of renal vascular occlusion, routine pyelographic examination was useful as a screening procedure because of readily appreciated changes: namely, nonfunction, marked disparity in renal size and/or function, and unilateral pyelonephritis. In 11 patients with borderline or normal urograms, differences in density of contrast at the pyelographic phase were difficult to appreciate. Differences in renal size as a reflection of volume of blood and solute in the kidney may be a better point of differentiation. In this small series a difference in circumference greater than 2 cm. seemed to provide a more sensitive scale of separation than either observation alone, measurement of length, or evaluation of contrast density. A film exposed 30 seconds after contrast injection facilitates measurement because of the nephrographic effect.

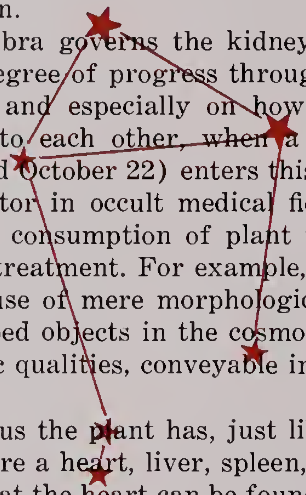
Astrology and Medicine — Libra, the Balance

Libra, seventh sign of the zodiac, is represented by a pair of scales, denoting the ideal balance between the spiritual and material forces throughout the cosmos. The sun enters Libra about September 22, the time of the autumnal equinox, to remain there for one zodiacal month before entering Scorpio. On June evenings the constellation of the Balance is clearly visible and easy to identify, as it consists mainly of only two bright stars: alpha Librae, approximately on the ecliptic, and beta Librae, a little above and eastward of its companion.



In Astrology's book Libra governs the kidneys - for better or worse, depending on the sun's degree of progress through the sign; on the lunar and planetary positions, and especially on how the celestial bodies are aspected with reference to each other, when a Libra native (one born between September 22 and October 22) enters this world.

As pioneer and innovator in occult medical fields and in astrotherapy Paracelsus advocated the consumption of plant products shaped like the human organs requiring treatment. For example, kidney beans for kidney diseases! Not alone because of mere morphological similarity, but rather because all similarly shaped objects in the cosmos were thought to be imbued with similar esoteric qualities, conveyable in essence from one entity to another.

"According to Paracelsus the plant has, just like man and animal, in it his organs. In the herbs are a heart, liver, spleen, etc. just as in man. This does not mean, he says, that the heart can be found in the plant as it can by man, but that it is present as a power and a virtue, like to the heart. In the first place Paracelsus seeks the conformable shape in the plants, - conformable to man and Cosmos, and he usually administered the plant which in shape conformed to the sick organ or part of the body, because according to his theorem both the sick organ and the agreeing plant took their shape from the same principle in the Cosmos; it therefore might be expected that the healthy principle in the plant would come to the aid of the sick principle of the part of the body."*

Preposterous? Maybe! But wasn't it Hamlet who said: "There are more things in heaven and earth, Horatio, than are dreamt of in our philosophy."

Pinch the Baby Before Landing

Robert L. Wick, M.D. has observed that middle ear trouble can occur when the plane lands and he recommends that in order to prevent the baby from having ear block the very small child should be pinched and made to cry for a very few minutes while coming down, as this would be preferable to hours of crying on the ground until the ear block can be relieved.

Diabetes Detection

Use of A Mobile Diabetes Detection Laboratory

WYMAN E. JACOBSON, M.D.*
LEONARD BENEDICT, B.CH.**
Minneapolis, Minnesota

THE EARLY discovery of currently undiagnosed cases of diabetes mellitus in the United States constitutes a real challenge to the medical profession, the public health services, and our entire society. The magnitude of the problem is reflected, at least in part, by the prevalence rate of this disease.

Incidence of Diabetes

In 1946 studies in Oxford, Massachusetts, revealed that 1.7% of the population had diabetes, with only 50% aware of the diagnosis.[1] On this basis it was estimated that there were approximately one million undiagnosed cases of diabetes in the United States at that time.

More recent surveys have revealed that by 1962 there were two million persons in the United States, or 1.8% of the population, with *known* diabetes.[2] The prevalence of the undetected cases still remains uncertain but is generally agreed to equal at least the number of known cases. On the basis of the U. S. Public Health Service survey from 1959 to 1962, there are more than four million persons, aged 18 to 79 years, in the United States who have a "true blood glucose" of 200 mg.% or higher, one hour after a challenge dose of 50 grams of oral glucose.[2] This estimate specifically excludes persons with known or questionable diabetes. Admittedly, not all of these persons with evidence of impaired glucose tolerance would prove by more rigid criteria to actually have diabetes mellitus. However, the probability of diabetes in this group must be considered quite high.

The striking incidence of this disease is only one factor indicating the need for newer and broader programs of case finding. Social, economic, and medical factors are equally compelling; the total benefits resulting from early diagnosis are immeasurable both for the community and for the pa-

tient. Prompt recognition of the disease can be expected to prevent most of the explosive symptoms. Some of the complications and associated manifestations can possibly be prevented or at least delayed in onset. In certain select individuals the early application of treatment may result in improvement of the decreased carbohydrate tolerance.

Method of Detection

Until recently most screening programs for diabetes have utilized urine-testing methods; however, there are certain disadvantages to urine tests for mass diabetes detection.

Urine vs. Blood

Our experience from 1959 to 1961 revealed that only 15% of the distributed urine-test kits were utilized and returned for processing.[3] Urine tests also provide a rather low relative sensitivity as compared to blood tests for diabetes detection.[4] Screening procedures for diabetes using blood specimens and the Clinitron have been previously described by Parker et al.[5] This report will briefly present our experience with the Clinitron in a mobile laboratory unit.

Mobile Laboratory

In 1963 the Twin Cities Diabetes Association put into operation a Diabetes Mobile Laboratory (Fig. 1). This unit was designed to meet the complete needs for patient registration, public education, and laboratory functions (Fig. 2). Special considerations were given to providing a complete power generator, adequate internal water supply, air conditioning, and heating units. Provisions were made to utilize local water and power supply whenever readily available. The laboratory section was equipped with the Hewson Clinitron using the Wilkerson-Heftman method for blood sugar determinations.[6] The ruggedness of the instrument and its relative simplicity of operation made it highly adaptable to the mobile laboratory.

Disposable Equipment

Special emphasis was placed on utilizing disposable equipment to a maximum. Sterile disposable lancets were used to obtain fingertip blood specimens. A highly accurate disposable micropipette was developed with the co-operation of Dade Reagents, Inc.* The pipettes are 12.5 cm. in length and constructed of nonsiliconized tubing calibrated to 0.10 ml. and 0.1125 ml. Detailed information for operation of the Clinitron can be found elsewhere in the literature.[7] A screening level of 130 mg.% was employed for all tests. Patients with known diabetes were excluded. Persons with a "positive" screening test were retested with a modified oral glucose tolerance test. This procedure consisted of obtaining fasting and two-hour blood specimens after a challenging dose of 100 grams of glucose. True blood glucose determinations were employed for the tol-

TABLE 3
Mobile Diabetes Detection Laboratory, 1963 Relationship of Food Intake to Results of Screening Test and Tolerance Tests

Time of Food Intake in 84 Persons	Number Positive	Modified Glucose Tolerance Test Abnormal	Borderline	Normal
Less than one hour	15	4	1	10
1 to 2 hours	36	23	2	11
		(67%)		
2 to 3 hours	24	17	2	5
3 to 4 hours	7	5	1	1
More than 4 hours	2	1	1	0

erance test. Values below 110 mg.% at these times were considered *normal* and values above 130 mg.% were considered *abnormal* for purposes of this study. Values of 110 to 130 mg.% were considered as *borderline.*

Results

For about six months during 1963 a total of 6,627 patients were tested (Table 1). The bulk of the persons screened were middle-aged asymptomatic employees of a few selected companies and persons visiting large shopping centers. Of the 6,605 satisfactory tests 174 or 2.6% had a "positive" screening result. The results of retesting with the modified oral glucose tolerance test are summarized in Table 2. Slightly less than one half (48.2%) of the "positive" reactors returned for the tolerance testing. In the 84 persons who were retested, 59.5% were distinctly *abnormal* and 8.3% were *borderline* in their response to a challenge dose of oral glucose. These results indicate a probable incidence of previously *unknown* diabetes mellitus in at least 1.5% of the tested population.

In the persons with a "positive" screening test one to three hours after food intake, 67% also had an abnormal oral glucose tolerance test (Table 3). Although the numbers are small, persons with a "positive" screening test within one hour of food intake are most apt to have a *normal* tolerance test.

Summary

1. Retesting of "positive" reactors with an oral glucose tolerance test revealed an incidence of 1.5% of previously undiagnosed diabetes mellitus in a small population sample.
2. Initial screening with the Hewson Clinitron at a value of 130 mg.% should be done one to three hours after ingestion of food in order to achieve a high degree of specificity.

Rudimentary Uterine Horn Pregnancy*

GEORGE SCHAFFHAUSEN, M.D.**
WILLIAM SPELLACY, M.D.**
Minneapolis, Minnesota

THE DIAGNOSIS of a ruptured uterine horn pregnancy requires keen suspicion and its management demands knowledge of the subject. To examine this problem a case will be presented and the literature reviewed.

Incomplete fusion of the mulliarian duct system with the formation of two uterine horns is responsible for this abnormality, as one of the horns remains rudimentary and does not participate in the formation of the cervix and vagina. The uterine tubes and ovaries are normal; but the urinary tract is frequently anomalous, too, indicating the close embryologic association of these two systems.

Pregnancy in a rudimentary horn is a rare occurrence. The first case was reported by Mauriceau in 1669.[1] There have been 329 cases reported, with an incidence of about 1 in 142,00 deliveries.[2] The pregnancy is more commonly found in the right horn.[3]

Fertilization may result from transperitoneal migration of either the sperm or the fertilized ovum. The former seems more likely, as the corpus luteum of pregnancy is found on the side of the rudimentary horn in 95% of the cases.[2] No communication between the rudimentary horn and the vagina has been reported in 11 out of 13 cases by one author.[4] John reported one patient in whom the rudimentary horn did not communicate grossly, but did communicate on microscopic examination; and he noted that this type of examination is not usually mentioned in the reported cases.[5] The improbability of transmigration has led Latto to believe that a canal is present at the time of fertilization but closes off due to the growth of the fibromuscular tissue of pregnancy.[6] Without this explanation it is difficult to account for the disposal of the menstrual blood. Followers of Sampson's theory of endometriosis would postulate that the gynatresia† of a rudimentary horn is associated with a frequent occurrence of endometriosis, and several such cases have been reported.[7] In 19 patients in one series reported by Gardner only five cases of endometriosis were diagnosed, which is less than the incidence of endometriosis in all gynecologic patients in the same hospital.[8]

If the communication with the uterus is through a small opening, one would expect dysmenorrhea. Indeed Merkal has reported 17 cases from the literature with dysmenorrhea and unilateral pelvic tumor. At laparot-

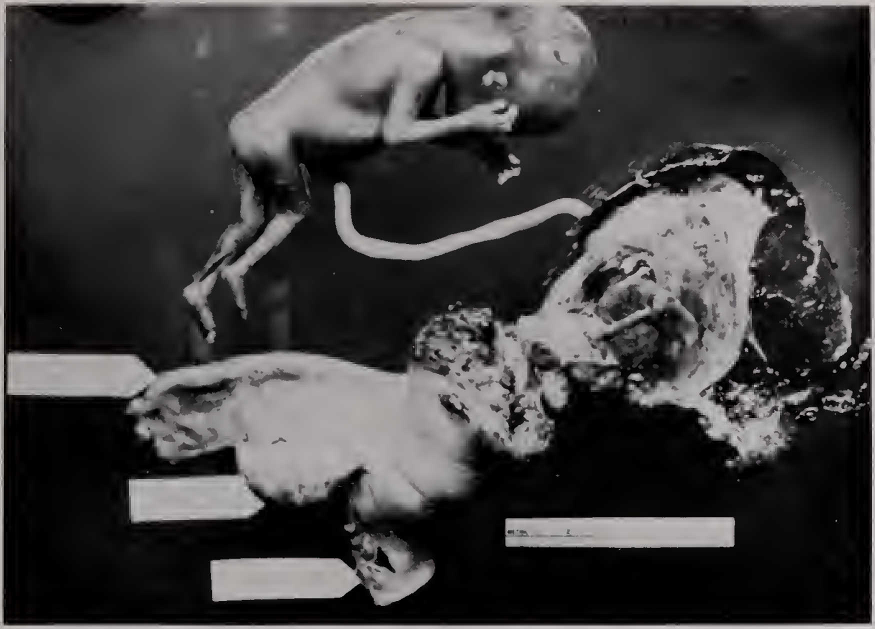

Fig. 1 — Resected rudimentary uterine horn with attached tube, ovary, and products of conception.

omy these patients were found to have a rudimentary horn with menstrual blood in the communicating horn. None of these patients was pregnant. Merckel named this the syndrome of unilateral gynatresia.[9]

The correct diagnosis of an intact rudimentary horn pregnancy is rarely made.[10] Abramson noted that since the horn is mobile and the gestation is late, a pelvic roentgenogram will show a fetal skeleton high in the abdomen. With this technique he diagnosed one of the few unruptured rudimentary horn pregnancies in the literature.[11]

The usual pregnancy complication is rupture of the horn, commonly occurring between the 16th and the 20th week of gestation and only rarely before the 12th week. This late rupture is attributed to the thick wall of the horn in contrast to the uterine tube. A high index of suspicion should be present in all ectopic gestations of more than 12 weeks. An occasional patient will manifest only mild symptoms and not be operated upon. At a later date, laparotomy for adnexal mass discloses a lithopedian with a healed ruptured rudimentary horn.[4] O'Leary reported a case of an abdominal pregnancy due to a healed ruptured rudimentary horn pregnancy which was carried to term and was delivered successfully by abdominal incision.[2]

The recommended procedure at laparotomy is removal of the ruptured horn and the accompanying uterine tube. The reason for removing the tube is to prevent future tubal pregnancies. January reported a patient with a ruptured rudimentary horn pregnancy where the accompanying tube and ovary were left in place. A subsequent pregnancy occurred in the noncommunicating uterine tube.[12] The main uterine defect should be closed in layers. Total hysterectomy need not be performed, as future pregnancies are possible in the remaining horn.[5] Several patients have been subjected to total hysterectomy because the condition was not recognized at the time of the operation.[4]

Case History

A 19-year-old white married female, who had had her last menstrual period on October 2, 1962, was admitted to the University of Minnesota Hospitals on January 18, 1963, with a history of morning sickness and breast engorgement. She had not seen a doctor for prenatal care.

Two days prior to admission, she had noted the onset of vague abdominal cramps radiating to both sides of the lower abdomen. The cramps continued and on the following day she had sharp lower abdominal pain associated with shoulder-strap pain. With the onset of nausea and emesis she sought medical advice. A private physician made a diagnosis of ruptured tubal pregnancy and referred her for treatment.

Her past medical history was normal. She denied any dysmenorrhea. Her physical examination including the pulse, blood pressure and temperature was normal with the exception of the pelvic and abdominal areas. The abdomen showed mild rebound tenderness and a mass consistent with a 20-week pregnancy. The fetal heart tones were inaudible and no fetal complexes were seen on fetal electrocardiogram. No adnexal masses were palpated. An irregular mass was present in the cul-de-sac. A culdocentesis produced blood.

Laboratory examination showed a hemoglobin of 8.7 grams % and a white count of 24,300. A chest film was normal. An abdominal film showed no fetal parts. The uterus could not be identified and the right psoas shadow was blurred.

Shortly after admission the blood pressure fell and blood was administered. At laparotomy the peritoneal cavity contained 2500 cc. of blood. A fetus, measuring 16 cm. from crown to heel and 11 cm. from crown to rump, was lying free in the peritoneal cavity with the placenta attached to the ruptured rudimentary horn of a bicornate uterus. The corpus luteum was on the attached ovary. The rudimentary horn was resected as well as the corresponding uterine tube (See Figure 1). A total of 3000 cc. of whole blood was replaced intravenously, and the postoperative course was uneventful.

Microscopic examination of the base of the horn showed no communication with the main part of the uterus. An intravenous pyelogram taken before discharge showed that the right kidney was ectopically low in the abdomen and there was duplication of the right ureter and the renal pelvis.

The patient returned to the prenatal clinic in her second pregnancy with an expected date of confinement of March 15, 1964. She had a normal prenatal course. On March 12, 1964, after a total labor of 11 hours and 17 minutes, she had an outlet forceps delivery of a normal 2680 gram male infant over a left mediolateral episiotomy using pudendal block anesthesia. The patient's post-partum course was normal.

Comments and Conclusion

This patient presented with the typical picture of a ruptured rudimentary uterine horn pregnancy. She was beyond 12 weeks' gestation and had the signs and symptoms of a ruptured tubal pregnancy. The lack of communication between the cervix and the horn on microscopic examination favors transmigration of the sperm. A urinary tract abnormality was demonstrated.

The subsequent delivery substantiates the necessity for conservative management.

Experience with Pargyline Hydrochloride

(Nonhydrazine Monoamine Oxidase Inhibitor)

as an Antihypertensive Agent:

Preliminary Observations in 32 Patients*

GERALD J. KAVANAUGH, M.D.**
SHELDON G. SHEPS, M.D.**
JOHN F. FAIRBAIRN, II, M.D.**
PHILIP J. OSMUNDSON, M.D.**
ALEXANDER SCHIRGER, M.D.**
Rochester, Minnesota

THE INTRODUCTION of pargyline hydrochloride for the treatment of hypertension represents a further effort to utilize an enzymatic blocking agent in the treatment of hypertension. Methyldopa, which interferes with the decarboxylation of dopa to dopamine in aromatic amine biosynthesis, was the first drug of this nature to become available commercially. Pargyline hydrochloride is a potent monoamine oxidase inhibitor of the nonhydrazine group first synthesized by Taylor.[1] The hydrazine structure (-NH-NH-), which was present in earlier monoamine oxidase inhibitors such as iproniazid, is not present in pargyline, and it had been suggested that this structural difference might decrease the likelihood of toxicity from the drug.[2] Pargyline is the first monoamine oxidase inhibitor to be introduced specifically as an antihypertensive agent, although the hypotensive effect of other monoamine oxidase inhibitors had been known previously. The drug is extremely effective in monoamine oxidase inhibition, but the exact manner in which it causes a lowering of blood pressure in man is not known.[3] As mentioned by Sjoerdsma,[2] the accumulation of various amines in the sympathetic ganglia or at the terminal nerve endings may be, in some manner, responsible for this effect.

Materials and Methods

This paper presents the data from 32 hypertensive patients who were treated with pargyline hydrochloride in the outpatient department of the Mayo Clinic. Of the 32 patients, 16 were men and 16 were women. The average age was 56, with ages ranging from 37 to 70 years. The Keith, Wagener, and Barker system of grading hypertensive retinal changes was used. Twenty-seven of the patients had group 2 hypertension, two had group 1, two had group 3, and one had group 4. Twenty-eight were classified as having essential hypertension, and four as having hypertension that was renal in origin (Table 1). Levels of blood pressure were determined daily in the sitting and standing positions for most patients during the initiation of treatment. Levels of blood pressure during the final or current period of treatment with pargyline were used in evaluating the results. The majority of the patients either had no previous treatment for their hypertension or had not received antihypertensive medications for at least several days prior to the initiation of therapy with pargyline. Twenty-two patients were treated initially with thiazide diuretics, to which pargyline was subsequently added. Five patients were treated with thiazide drugs in addition to another antihypertensive agent at the time pargyline was instituted (two with guanethidine sulfate, two with hydralazine hydrochloride, and one with reserpine). In five patients, treatment was started with pargyline hydrochloride alone. Serial determinations of hemoglobin levels, leukocyte counts, differential counts, serum glutamic oxaloacetic transaminase (SGOT) levels, blood urea values, and urine specimens were carried out for most of the patients.

20 to 29	5
10 to 19	4
5 to 9	3
4 or less	14

Early in the study, the initial drug dosage was 10 mg., given as one dose at bedtime, increased rather rapidly at two or three-day intervals in increments of 10 mg. The cumulative action of the drug soon became apparent, and the increments then were made at weekly intervals, with a usual starting dose of 25 mg. The average daily dose of pargyline for the entire group was 32 mg., with a range of 10 to 100 mg.

The clinical characteristics of the patients are summarized in Table 1. In seven patients, it was necessary to discontinue the use of pargyline because of side effects. Angina pectoris developed in one patient, and therapy was stopped after four days. The other six patients had shown reasonably satisfactory responses to the drug before it was discontinued because of side effects (insomnia in two, fluid retention in two, and congestive heart failure in two). Three patients receiving full doses of thiazide diuretics showed no apparent response to pargyline when it was added to the program; thus, the use of the drug was discontinued. In two others, tolerance developed to the medication and therapy was stopped: in one patient at six weeks and in the other at 28 weeks.

Results

The results of treatment with pargyline hydrochloride are summarized in Tables 2 and 3. The reduction of mean blood pressure was 10 per cent or greater in 19 of 31 patients; the patient in whom therapy was stopped after four days was not included in the total calculation of results.

Reduction of Blood Pressure

In patients treated with pargyline alone, the blood pressure decreased an average of 16 mm. Hg systolic and 10 mm. Hg diastolic. In patients receiving pargyline in addition to a thiazide diuretic, the blood pressure decreased an average of 20 mm. Hg systolic and 12 mm. Hg diastolic. In the patients receiving pargyline, a thiazide, and additional antihypertensive therapy, the average decrease of blood pressure was 40 mm. Hg systolic and 22 mm. Hg diastolic. The concomitant use of pargyline and other antihypertensive drugs had an additive effect in lowering blood pressure. This was most strikingly demonstrated in one patient who, at the time pargyline was added to her program, was receiving 450 mg. of guanethidine and 120 mg. of pentolinium tartrate (Ansolysen) in addition to a thiazide diuretic with poor control of her hypertension. Her blood pressure is currently under good control with 50 mg. of guanethidine and 100 mg. of pargyline daily, plus a thiazide diuretic.

Insomnia

The major and minor side effects precipitated by the use of pargyline hydrochloride are listed in Table 4. Insomnia and retention of fluid were the most common complaints. These side effects have been noted in most other reports.[4-8] In two patients, the use of the drug was stopped because of insomnia. The loss of sleep resulting from pargyline

therapy was very disturbing to some patients, but administration of the dose in the morning did not seem to change the pattern of insomnia. One patient with pre-existing angina pectoris experienced anginal attacks of greater severity and frequency while being treated with pargyline hydrochloride, and another patient had symptoms of angina pectoris first appear after initiation of therapy.

Fluid Retention

The retention of fluid, as manifested by peripheral edema and rapid fluctuations in weight, was of particular concern to the women who underwent treatment. We believe that fluid retention resulted in the development of congestive heart failure in two patients. The concomitant use of a thiazide diuretic alleviated this difficulty to a certain extent but did not abolish it. Postural dizziness with near syncope occurred in three patients despite efforts to caution them concerning the orthostatic* effect of the drug. Our early, rather frequent increases in dosage may have been responsible for this effect in these patients.

Bronchial Spasm

One patient developed symptoms of bronchial asthma while being treated. This patient, a 64-year-old woman, had been maintained rather well with a thiazide diuretic and 10 mg. of pargyline daily. After a number of weeks of therapy, hospitalization was necessary because of an acute episode of severe wheezing. There was no previous history of asthma. Supportive measures to alleviate the bronchospasm were effective initially; but two weeks later a similar episode occurred, and the patient succumbed. Pargyline therapy had been continued until shortly before her death. While it is difficult to state unequivocally that a relationship to pargyline hydrochloride was present, no other therapy was given prior to the first asthmatic episode, and the sudden development of severe bronchospasm was most striking.

Minor Side Effects

Minor side effects were noted in five patients. These included dry mouth in two, faintness in one, constipation in one, and nausea in one (Table 3). None of these side effects, however, necessitated the stopping of the drug therapy.

A mood-elevating effect, while difficult to evaluate, was observed in some of the patients. This was noted particularly in one patient, who had become quite depressed during therapy with guanethidine.

During this study no abnormalities were found in results of serial laboratory determinations. In those patients with pre-existing azotemia,* aggravation of the nitrogen retention did not occur. The absence of laboratory data indicating hepatotoxicity may be a reflection of the nonhydrazine formulation of this drug.

Discussion and Conclusions

In 20 of the 32 patients, treatment with pargyline hydrochloride proved to be reasonably effective and was well tolerated by the patients. Nevertheless, unsatisfactory responses in 12 of the patients, either because of side effects, tolerance, or lack of antihypertensive action, emphasizes that, despite intensive research by pharmacologists and physicians, an ideal therapeutic agent for hypertension must still remain the hope for the future. More recent information concerning possible adverse reactions during the administration of monoamine oxidase inhibitors and the ingestion of aged cheese,[9] fermented beverages, or medications containing sympathomimetic amines should alert the physician to the need for caution when using this class

of drugs in the treatment of hypertension. Admonition of the patient to avoid such exposures will never completely eliminate the possibility of their occurrence. With certain reservations, we believe that pargyline hydrochloride is a reasonably effective and well tolerated agent. Its use should be restricted to those patients with moderately severe hypertension and with evidence of good cardiac reserve. Patients who become depressed while being treated with other agents may be treated advantageously with pargyline, utilizing its mood-elevating effect. Because the mechanism of action is unknown and because of the potential development of unexpected reactions, the prescribing physician must attend the use of pargyline with greater than usual caution and observation. Continued study of the drug should help in delineating the place of pargyline hydrochloride in the treatment of hypertension.

Acknowledgments

Miss Karen Greenlee gave valuable technical assistance in data calculation, and pargyline hydrochloride was supplied for this study as Eutonyl by Abbott Laboratories, North Chicago, Ill.

SUPRASPINATUS SYNDROME

This is a general term used to include a variety of lesions involving the subacromial bursa, the supraspinatus tendon, and may include tears, detachment, or calcification of the tendon, tendonitis, or lesions of the greater tuberosity.

Symptoms include aching in the region of the shoulder joint with referred pain into the neck, outer side of the arm, or dorsum of the forearm. There is loss of power and inability to initiate or sustain abduction. In the middle range of abduction, movement of the tendon may impinge on overlying processes and become compressed between the humerus and acromion, causing pain. Any movement may bring the lesion in contact with the acromion and causes muscle spasm. When this condition becomes chronic it may develop limitation of motion of the shoulder and disuse atrophy.

The prognosis in this condition is usually good. Surgical removal of calcium may be indicated, or the pinpoint area may be injected with hydrocortone. Bosworth, JAMA 117:422, 1941.

By taking revenge, a man is but even with his enemy; but in passing over it, he is superior. — Francis Bacon

IT'S THE LAW

Doctor Liable for Vocal Cord Paralysis Following Subtotal Thyroidectomy

The patient established a *prima facie* case of negligence, since it could be inferred from the facts that she had a soft, feminine voice before his performance of a subtotal thyroidectomy, but her left vocal cord was found to be permanently paralyzed immediately after the operation, that the doctor had severed or injured the recurrent laryngeal nerve, the Alaska Supreme Court ruled.

The doctor noted in his operative report that the recurrent laryngeal nerve was visualized on the right side. It was also noted in the report that there was a symmetrical marked enlargement of both lobes of the thyroid gland, but no mention was made of anything irregular in the recurrent laryngeal nerve's appearance or course.

The patient's evidence established that immediately after the operation her previously soft, feminine voice was hoarse and that this condition has persisted. Postoperative examination disclosed that her left vocal cord was permanently paralyzed and there was expert testimony that the hoarseness indicated that the recurrent laryngeal nerve was injured in the operation.

The doctor's operative report, which was not dictated until the day after the operation, merely stated the ultimate facts connected with each step of the operation on the right side and noted that the same procedure was followed on the left side, without specifically stating that the recurrent laryngeal nerve was visualized on the left side.

The patient contended that the operation was performed without her informed consent. She testified that the referring doctor told her that the operation was nothing more than a tonsillectomy and that she might not have consented to it if she had been informed of the risk of losing her voice. A doctor does not have to inform a patient of all the risks involved in an operation but may tailor his warning to the particular patient, the court said.

The patient contended that the doctor's operative report should not have been admitted in evidence because, having been made after he knew her voice was not normal, it was self-serving. The admission of the report was not prejudicial to the patient. There was no jury to be misled, the record indicated that the trial judge used abundant caution in admitting it, and there was nothing in the report itself that was prejudicial.

Diabetes Mellitus and Surgery

BEN I. HELLER, M.D.*
Oklahoma City, Oklahoma

PATIENTS WITH diabetes mellitus may develop any of the diseases for which major or minor surgical procedures are required. Additionally, the diabetic patient is particularly prone to gangrene of the extremities, cholelithiasis and cholecystitis, carbuncles, and other suppurative processes such as perinephric abscess. The intervention of a disease process which may require surgery frequently demands changes in the traditional pattern of management of diabetes in both the preoperative and postoperative periods.

Moreover, because of the development of complications of diabetes mellitus and due to the nonspecific stress of surgery, the diagnosis of diabetes may be first entertained when the patient is admitted to a surgical service. In a recent review,[1] newly discovered diabetes was found in 23 percent of 487 patients undergoing surgical procedures. In view of these data which confirm the experience of others, it would appear that screening for diabetes by the determination of the fasting and two-hour postprandial blood glucose, particularly in these patients over the age of 40, would be a highly desirable preoperative measure. It should be emphasized that patients admitted to emergency wards frequently receive glucose solutions intravenously shortly after admission. In such instances, glucosuria noted in the first urinalysis may be disregarded and the diagnosis of diabetes mellitus mistakenly overlooked.

On the other hand, the urinalysis may be negative for glucose when the so-called "renal threshold" for glucose is elevated. It should be noted that the "renal threshold" is not a single variable but is dependent upon three variables. These are the tubular reabsorptive capacity for glucose, the glomerular filtration rate, and the arterial plasma concentration of glucose. Under circumstances during which the glomerular filtration rate may be further reduced by decreased renal perfusion pressure due to anesthesia or unrecognized plasma volume depletion, the urine may be free from glucose even in the presence of moderate hyperglycemia.

Influence of Diabetes Mellitus on Diseases Requiring Surgery

Increased mortality and morbidity are well recognized phenomena in diabetic patients undergoing surgery.[1,2] The chief factors in the increase are as follows:

1. The degree of control of the diabetes, particularly the presence or absence of ketoacidosis; 2. the prevalence of vascular disease; 3. the greater susceptibility of the diabetic patient to infection.

---

*Departments of Laboratory Medicine and Medicine, University of Oklahoma Medical Center.

Vascular Disease

Generalized vascular disease is more common in middle-aged and elderly diabetic subjects than in nondiabetic subjects of the same chronological age. Younger patients with diabetes of long duration may also have generalized vascular disease involving the cerebral, coronary, renal, and peripheral arteries. Although it is to be readily expected, it is not generally appreciated that vascular accidents following surgery are more common in diabetic patients. Acute myocardial infarction and congestive heart failure as a manifestation of coronary insufficiency are particularly prone to occur postoperatively. The precipitating factors are probably multiple in origin. Periods of hypotension during anesthesia and surgery may cause decreased perfusion of diseased vessels. The clinical manifestations of cerebral, myocardial, and renal ischemia may then be noted postoperatively. Uncontrolled diabetes, especially in the presence of diabetic keto-acidosis, may be associated with large extracellular and plasma volume deficits. Hypotension may or may not be present, depending upon the degree of peripheral and splanchnic vasoconstriction. Failure to correct the volume deficits will cause decreased cardiac output and result in decreased organ perfusion. The same phenomena may occur after surgery if the management of the diabetes is grossly inadequate.

Infections

Although increased susceptibility of the diabetic patient to infection has long been a clinical axiom, the pathogenesis is poorly understood. In patients with poorly controlled diabetes it is possible that this merely represents decreased resistance secondary to negative nitrogen balance, derangement of electrolyte and water balance, and disordered cellular metabolism. In patients with diabetic keto-acidosis, increased plasma adrenal-corticosteroid concentrations may also play a role. It is further conceivable that there may be disorders of the immune mechanism which are a fundamental part of the diabetic disease process.

Influence of Surgery on Diabetes Mellitus

Uncontrolled diabetes is readily precipitated by most surgical diseases. Superimposed upon already existent insulin insufficiency are the hyperglycemic effects of stress.[3] The stress reaction is characterized by increased sympathicoadrenal and adrenal corticosteroid activity. The resultant increase in circulating epinephrine causes the breakdown of liver glycogen and further increase in blood glucose. The increase in plasma glucocorticosteroids results in increased production of glucose from protein stores (gluconeogenesis). General anesthesia itself undoubtedly contributes to the impairment of carbohydrate metabolism, although the specific effects of various anesthetic agents are a matter of controversy.[4] The ultimate effects of the surgical diseases, of anesthesia, and of surgery are further impairment of carbohydrate metabolism and an increase in insulin requirements.

Management of the Diabetic Patient During the Surgical Period

The goal of management of the diabetic patient during the three phases of the surgical period is the maintenance of metabolic homeostasis. Three factors which must be considered in the attainment of this goal are the avoidance of keto-acidosis, the prevention of hypoglycemia, and the correction of electrolyte and water deficits. It is readily apparent that concomitant cardiovascular renal disease, anemia, and infection must also be carefully evaluated and vigorously treated prior to surgery.

Depot Insulin vs. Regular Insulin

A difference of opinion exists as to the use of depot insulin or regular insulin on the day of surgery and postoperatively. Advantages and disadvantages can be noted with either therapeutic program. Some competent authorities[3,5] prefer NPH insulin with supplementary doses of regular insulin as required, while others[6,7] prefer the administration of crystalline insulin at specific intervals. Both modes of therapy have been used successfully in our Medical Center. It would appear that careful evaluation of the total patient and the adoption of a specific therapeutic program tailored to the patient is of greater importance than the type of insulin which one selects for therapy. Failure of total patient evaluation and lack of appreciation of the goals of therapy may lead to tragic consequences and may, indeed, be lethal. The proper therapeutic philosophy has been superbly summarized by Rynearson[8] who stated that "while many surgical conditions require special attention, diabetes requires only constant attention."

Guidelines for Proper Therapy

1. Total patient evaluation is absolutely essential to proper diagnosis and therapy. A precise history and a meticulously performed physical examination are of major importance.

Case History

A 21-year-old man with diabetes of five years' duration was admitted with diabetic coma. The presence of abdominal rigidity and the absence of bowel sounds suggested the possibility of intra-abdominal disease. A careful history from the mother revealed that intense headache, fever, nausea, and vomiting had been present for 36 hours prior to the onset of coma. Physical examination revealed nuchal rigidity. Clinical workup led to a diagnosis of meningococcal meningitis. Proper therapy of the meningitis and diabetic coma led to recovery.

2. Diabetic keto-acidosis may simulate numerous types of acute surgical diseases of the abdomen. This may occur with or without acute gastric dilatation. In some instances the history and physical examination may help delineate the two conditions. In other instances the diagnostic dilemma may not be solved until the keto-acidosis has been successfully treated.

3. Surgery should never be performed on a patient with classical diabetic coma before therapy has corrected the metabolic defects and before a definitive diagnosis is reached.

4. The urgency of emergency surgery is frequently overemphasized and such surgery is too frequently performed before adequate total patient evaluation and the therapy related thereto are carried out.

5. Treatment of infection and the drainage or removal of suppurative foci may be followed shortly by a dramatic reduction of insulin requirements.

6. Hypoglycemia may be readily overlooked in patients with complex symptoms and findings. The highest incidence of hypoglycemic reactions occurs in those patients who have received NPH insulin with supplementary doses of regular insulin.

7. The minimal definitive surgical procedure of the shortest duration should be performed. Regional or spinal anesthesia should be used wherever feasible. Early ambulation and early resumption of oral feedings may facilitate the control of the diabetes.

Management of the Nonketonic Diabetic Patient for Elective Surgery

Preoperative Cautions

The patient may continue on his usual treatment until the day of surgery, although some increment in insulin dosage may be necessary because of physical inactivity during the preparatory period. It is well to obtain a fasting blood glucose and serum electrolyte determinations as baseline studies prior to surgery. Accurate daily weights should be recorded during the preparatory period and continued during the postoperative period. Such records are absolutely mandatory* for proper fluid therapy.

Day of Surgery

On the day of surgery the therapeutic regimen of Duncan[6] is preferred. There are, however, no serious objections to other therapeutic programs[1,5] which utilize long-acting insulin. The possibility of hypoglycemia must be kept constantly in mind, particularly when supplementary doses of regular insulin are given later in the postoperative period. One fourth of the previous day's insulin dosage is given subcutaneously as crystalline insulin on the morning of surgery just prior to the administration of one liter of ten-percent glucose in water, administered intravenously at the rate of 20 to 30 drops per minute. Fifty grams of glucose are administered intravenously every six hours postoperatively in a volume calculated to meet the daily fluid volume requirements. This is preceded by the subcutaneous injections of one fourth of the previous day's dosage of insulin. Increments or decrements in insulin dosage are determined by the clinical course, as monitored by blood and urine glucose determinations and by the presence or absence of ketonuria and ketonemia. It will not generally be necessary to give sodium chloride during the first 24 hours, but this should be given subsequently to replace calculated deficits. Approximately 60 to 100 milliequivalents of potassium per day are required to prevent potassium depletion. The determination of the urinary concentration of sodium and potassium is a useful guide to the daily requirements for sodium and potassium replacement. Rigid control is not sought nor is it desirable. When oral feedings are resumed, they are administered every six hours according to the same plan until the patient can again receive his customary diet and insulin therapy.

---

Management of the Diabetic Patient for Emergency Surgery When Diabetic Coma is Present

It is obvious that emergency surgery can not be performed in a patient in diabetic coma irrespective of surgical indications.

Guidelines for Therapy

1. Adequate regular insulin must be given early. In our clinic, we customarily give 100 units of regular insulin subcutaneously and 100 units intravenously as soon as the diagnosis is made. Further insulin dosage is determined by monitoring the patient at two-hour intervals with blood glucose and urine glucose determinations. The serum acetone test serves as a useful guide in estimating the requirements for insulin.

2. Isotonic saline is nonphysiologic. Isotonic saline contains 154 meq./L. of sodium and 154 meq./L. of chloride and is therefore markedly hypertonic as regards the chloride ion, and slightly so as regards the sodium ion. The administration of a solution with such an anion concentration is decidedly unphysiologic in a patient who is already in metabolic acidosis. Water and electrolyte replacement is carried out with a diabetic repair solution consisting of 500 ml. of saline, 500 ml. of distilled water, and one ampule of sodium bicarbonate containing 44 meq. The ionic content of this solution in milliequivalents per liter of solution is as follows: sodium 122, chloride 77, and bicarbonate 44.

3. Sodium bicarbonate is indicated early. The studies of Kety[9] have indicated that survival in diabetic coma is largely determined by the degree of reduction in cerebral oxygen utilization. This is correlated with the reduction of blood pH. Kety's results demonstrate that it is possible to bring the blood pH toward normal quickly by giving small amounts of sodium bicarbonate intravenously.

4. Glucose is not indicated early. The administration of glucose early will further increase the hyperosmolarity of the extracellular fluid and thus increase cellular dehydration.

5. Water loss may amount to seven to ten percent of the body weight.

6. Potassium replacement need not begin until the fourth to eighth hour of therapy, since the initial serum potassium is usually elevated. The elevation of the serum potassium initially in the face of an actual cellular deficit of potassium is due to the shift of potassium from the cells to the extracellular fluid, while hemoconcentration and poor renal function are present. This may be given by either the oral or intravenous route. If intravenous administration is required, 60 meq./L. may be given in a three to four-hour period.

7. Plasma or whole blood may be indicated to combat shock.

8. Overhydration should be avoided.

After successful therapy of the diabetic coma, total patient evaluation can then determine whether emergency surgery is required.

Summary

1. Newly discovered diabetes is frequently encountered on a surgical service due to the nonspecific stress of surgical diseases and the resultant impairment of carbohydrate metabolism, and due also to diabetic

complications which require surgery for their correction.

2. Total patient evaluation by precise history, a careful physical examination, and indicated laboratory studies are imperative before any surgical measures are taken.

3. Metabolic defects should be corrected as nearly as possible before surgery is performed.

4. The goals of therapy postoperatively are the avoidance of keto-acidosis and hypoglycemia and the prevention of electrolyte and water imbalance.

WHAT'S YOUR DIAGNOSIS?

A fifty-five-year-old executive complained of right lower abdominal pain of three days duration. Initially it was associated with an urge to move his bowel, but normal daily bowel movements did not alter the pain. He had no nausea, dysuria, or fever, and his appetite remained normal. One month previously he had noted a similar episode of pain which had spontaneously subsided in two days. Except for an uneventful repair of a left inguinal hernia six months previously, he had been in good health.

Physical examination disclosed an afebrile man in no acute distress. There was tenderness and guarding in the right lower abdomen, but no abnormal masses were palpated. Bowel sounds were normal and there was no rebound tenderness. Rectal examination aggravated the pain, particularly on the right.

Admission chest X ray, hemoglobin, and urinalysis disclosed no abnormality. The leucocyte count rose from 12,000 to 14,000 overnight, with a relatively normal differential. Exploration was carried out. A normal appearing appendix was found lateral to the hepatic flexure.

What is your diagnosis? See page 746.

An admirer once asked James Barrie how he managed to grow old so gracefully. He answered, "My dear lady, I give all my time to it." — Walter Winchell

For just experience tells, in every soil, That those that think must govern those that toil. — From The Traveller — Oliver Goldsmith

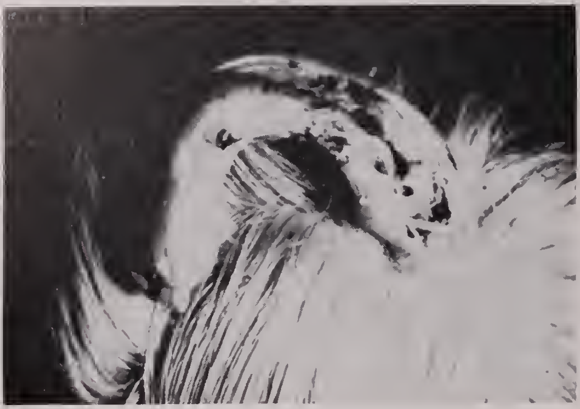

Fig. 7 — Cutaneous horn. The scalp is a common location.

Precancerous

THE TERM "precancerous" has been used loosely by dermatologists to include dermatoses in which the incidence of carcinoma is no greater than should be expected when various factors such as age, exposure to sunlight, chronic irritation, and effects of previous treatment are considered. The term "precancerous" dermatosis should be confined to true but rare instances of Bowen's disease, various types of leukoplakia, senile keratosis, cutaneous horn, and keratosis resulting from the ingestion of arsenic, exposure to tar, and iodizing radiation. In at least 20% of these disorders carcinoma eventually develops and is usually of the squamous-cell type. In the past, other diseases such as seborrheic keratoses, certain nevi, tuberculous and stasic ulcers, lupus vulgaris, lupus erythematosus, epidermal cysts, and scars following burns have been incorrectly labeled precancerous, since the incidence of carcinoma varies from only a fraction of 1% to about 5% in these disorders. If the term precancerous is used as it has just been defined, it has a meaning both clinically and histologically, and is of value from the standpoint of prognosis and treatment.

Bowen's Disease

Bowen[1] (1912) described two cases in which there was a solitary lesion which resembled a noduloulcerative syphilid, and he stated that the disorder was a precancerous dermatosis. The early nodular lesions became dull red, infiltrated, crusted plaques by peripheral extension followed by superficial ulceration. A rolled pearly border was rarely present.

The disorder occurs usually on the trunk, although the face and extremities may be involved. In one of Bowen's cases the disease persisted for 19 years without increase in the size of the lesion or development of metastasis. Subsequently, however, many cases have been reported in which squamous-cell epithelioma developed with metastasis and death. The term precancerous dermatosis of Bowen should be limited to lesions which resemble a noduloulcerative syphilid. There have been many cases reported as Bowen's disease which were in reality examples of superficial epitheliomatosis.

Surgical excision or electrodestruction are the methods of choice in the treatment of the disorder. The lesions are relatively radioresistant, hence radiotherapy is usually contraindicated. However, it is of value occasionally in superficial plaques.

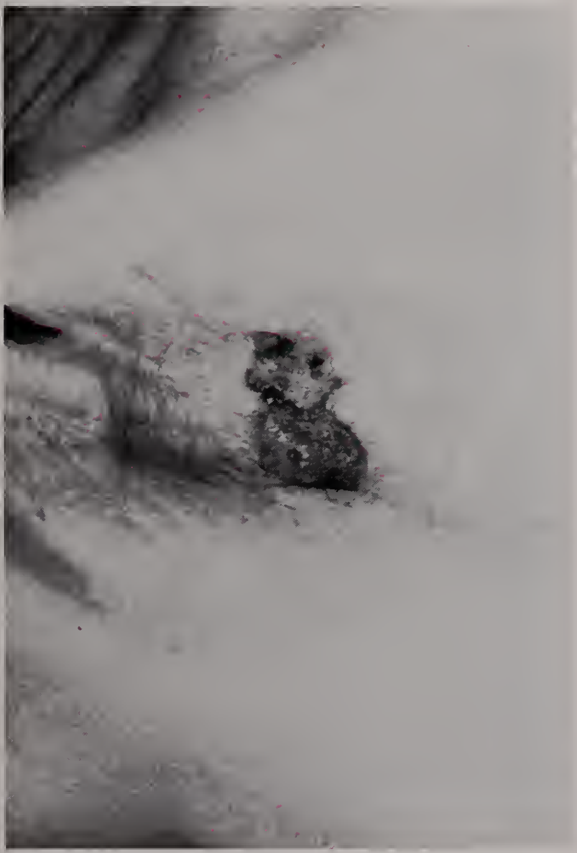

Fig. 1 — Bowen's disease in the axilia. The arcuate nodular lesion simulates a tertiary syphilid.

Leukoplakia

The term leukoplakia is derived from the Greek, meaning white plaque. The word leukokeratosis implies that the lesion has become thickened and elevated.

Leukoplakia usually occurs on the inner surfaces of the lips and cheeks and on the dorsum and edges of the tongue. The disorder is not confined to the oral cavity and may occur on the male and female genitals. The lesions are usually dull white and occur as patches, isolated points, or bands. The incidence of carcinomatous change in leukoplakia is difficult to determine but has been estimated to be from 20 to 30%.

Leukoplakia results from chronic irritation and trauma such as smoking, jagged or carious teeth, and poorly fitting dentures. About 95% of the cases occur in men. Women who have the disorder usually have improperly fitting dentures or are heavy smokers. Syphilis as an etiologic factor is unimportant.

Treatment consists of the removal of local irritants, proper adjustment of dentures, cessation of smoking, and proper care of the teeth. Lesions which become verrucous, fissured, or ulcerated should be destroyed by electrodesiccation or cauterization. They are radioresistant. Surgical removal is occasionally indicated when the lesions are extensive.

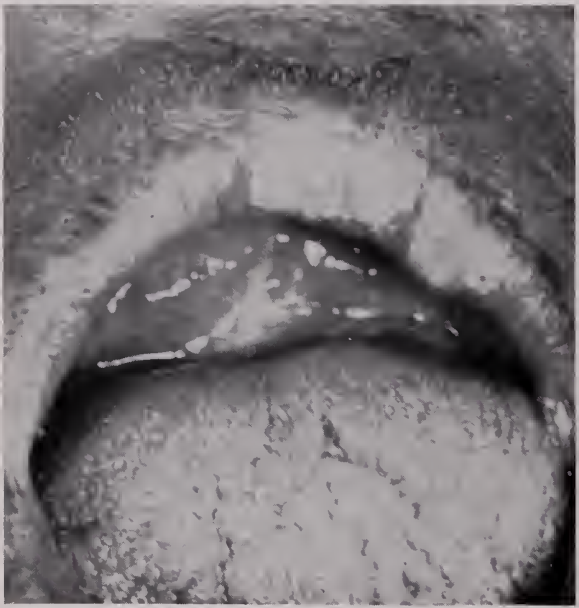

Fig. 2 — Extensive leukoplakia of the upper lip. The lower lip is involved more frequently.

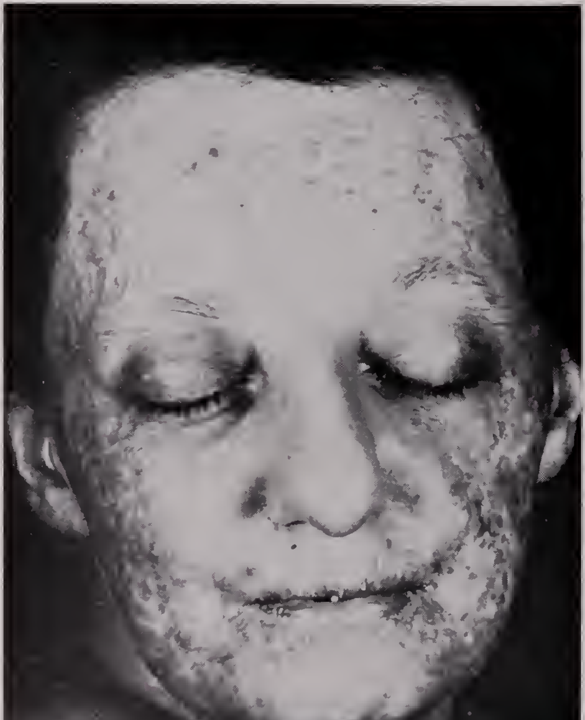

Fig. 3 — Chronic radiodermatitis showing hyper and hypopigmentation and numerous keratoses.

Radiodermatitis

Acute Type

First degree radiodermatitis consists of erythema with slight burning, itching, and scaling which disappears after a few days or weeks. There may be temporary alopecia, and pigmentation may develop later.

In second degree radiodermatitis there is edema, intense erythema and vesiculation. In a few days exudation, erosion, and crusting ensues. There is a loss of hair which may be permanent. The activity of the sebaceous and sweat glands is impaired. Atrophy and telangiectasias appear several months later.

Third-degree radiodermatitis is characterized by necrosis and ulceration. Healing is usually slow and may take several months; in some instances the ulcerations are so indolent that they never heal.

Chronic Type

This form of radiodermatitis may develop after the acute type or insidiously as a result of an excessive number of fractional (suberythema) doses. The skin is dry, thin, smooth, shiny, and sensitive to trauma. Itching and burning are prominent symptoms. There is both hyper and hypopigmentation and telangiectasia. The nails may be striated, discolored, brittle, or lost. As the disorder progresses multiple keratoses appear. Carcinoma develops in about 20% of the cases in which the damage has been greater than just simple telangiectasia. It is usually squamous rather than basal cell in type. Sarcoma may arise in areas of radiodermatitis.

The simpler forms of radiodermatitis can be treated successfully with measures which are used for corresponding phases of dermatitis due to other causes. Ointments or creams containing a steroid and an antibiotic are helpful in first degree radiodermatitis. If vesiculation is present moist compresses of Burow's solution may be employed. In severe cases where there is necrosis and ulceration, excision of the entire lesion followed by grafting is indicated. The procedure should be employed many months after the beginning of the dermatitis when progression has ceased.

Keratoses

Arsenical Type

Keratoses which follow the ingestion of inorganic arsenic appear as discrete, warty lesions usually on the palms, fingers, and soles. They are generally symmetric and surmounted by a small, black shiny peg of keratin. Fissuring is common. Keratoses following the ingestion of organic arsenic such as arsphenamine are rare but have been reported. Keratoses may develop within a month after the first ingestion of arsenic or as long as 30 years later. Once the lesions appear they usually persist and 20% of the cases eventuate in epithelioma even though there is no further ingestion of arsenic. There seems to be an individual susceptibility or tolerance to arsenic, because some patients are able to take the drug for many years with only mild pigmentation and keratoses, while others develop keratoses and epitheliomas followed by metastasis and death with only small amounts of the medication.

Treatment for arsenical keratoses is unsatisfactory. When epithelioma develops, surgical excision is the method of choice. In some cases when carcinoma is present on a digit or on the palms and soles, amputation may be necessary.

Seborrheic Type (*Verruca Senilis*)

Seborrheic keratoses are not precancerous but should be discussed briefly because they are confused sometimes with senile keratoses. The former are more superficial and softer than the senile type. Seborrheic keratoses as a rule are multiple and are raised slightly above the surface of the surrounding skin. Their color varies from light brown to almost black, and they usually occur on the face, back, and chest. Removal of the loosely attached greasy crusts reveals a raw pulpy base. They begin in middle age. Carcinoma develops in only 1 or 2% and is almost always of the basal-cell type.

Seborrheic keratoses should not be treated with X rays or radium; they can be destroyed easily by means of cauterization or desiccation.

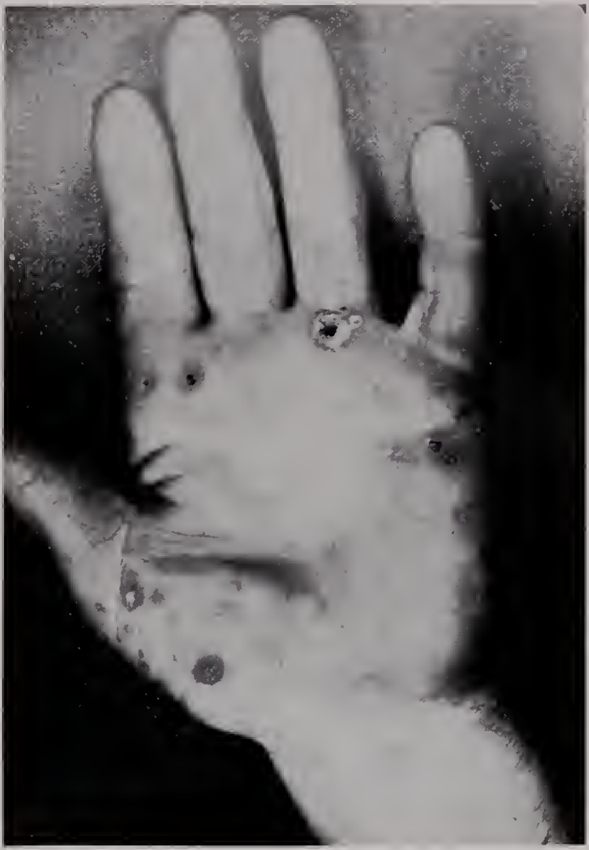

Fig. 4 — Arsenical keratoses. The lesions mimic ordinary warts.

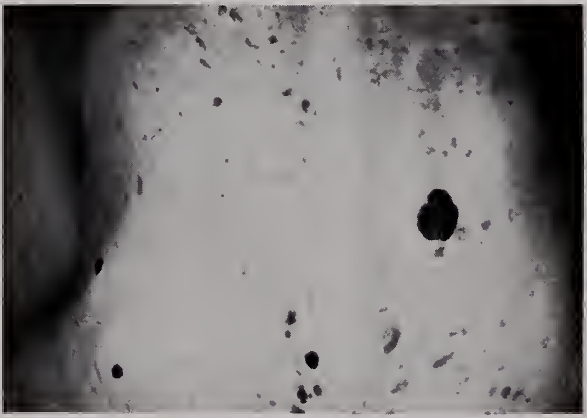

Fig. 5 — Multiple seborrheic keratoses on the back. These lesions should not be regarded as "precancerous."

Senile Type

These lesions are seen most frequently in people who have exposed to sun and wind for many years, and appear chiefly on exposed parts, especially the hands and face. They may be single or multiple and are usually dark brown or black. The surface of the

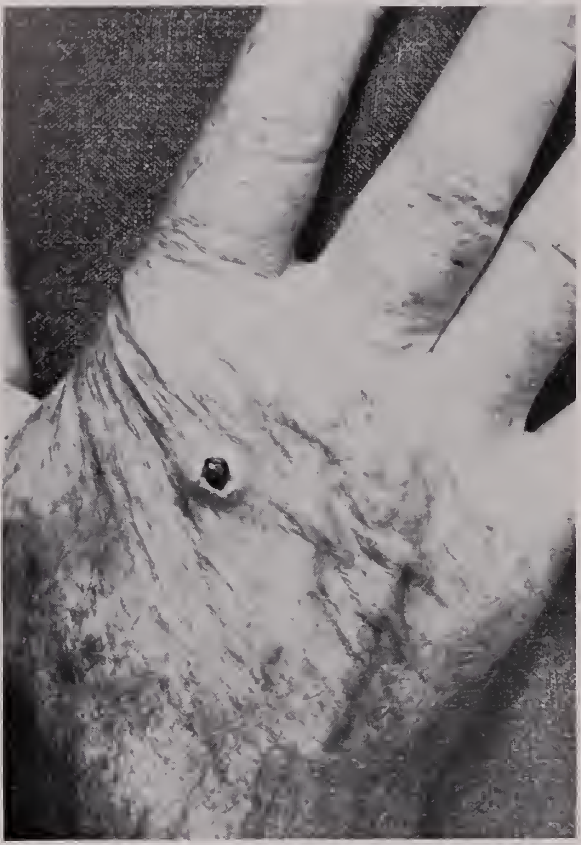

Fig. 6 — Senile keratosis plus early squamous-cell epithelioma.

involved skin is uneven, bleeds easily, and is sometimes superficially ulcerated. Senile keratoses are firmer, more discrete, and more raised from the surface of the skin than seborrheic keratoses. In 20 to 25% of the cases squamous-cell carcinoma develops in one or more of the lesions.

Senile keratoses are radioresistant and should be destroyed by means of cauterization or desiccation.

Cutaneous Horn

These lesions are rare and may resemble similar growths in lower animals. The majority of cutaneous horns develop from senile keratoses, and epitheliomatous changes occur frequently. Cutaneous horns are similar to senile keratoses except that there is an excessive development of keratotic material. They may be cylindric, straight or twisted, and usually occur on the scalp and face, although sometimes other areas are affected. The color varies from light brown to black. They may be short or several inches long.

Treatment is essentially the same as for senile keratosis. If the horn is small and shows no evidence of carcinoma it may be destroyed by cauterization or desiccation. A larger lesion, especially one in which malignant change is suspected, should be excised.

Gastric Cancer*

Treatment of

GEORGE T. PACK, M.D.**
IRVING M. ARIEL, M.D.**
New York, New York

CANCER OF the stomach accounted for 21,522 deaths in the United States in 1957 and for 1,538 deaths in New York City in 1957. The incidence of this neoplasm is three times as great in Japan, Finland, and Chile as in England, Canada, and the United States. Trapeznikov reports that gastric cancer is the most frequent malignant tumor in the Union of Soviet Socialist Republics, accounting for 30 per cent of all cancers.

Decline in Stomach Cancer Rates

The decline of stomach cancer in the United States and 23 foreign countries has been confirmed by William Haenszel of the Biometry Branch of the National Institutes of Health, U.S.A. Some of his key findings may be adumbrated as follows:

1. A steady decline in stomach-cancer rates in the United States for both men and women during the past several decades, a trend duplicated in some, but not all, foreign countries. (Age-adjusted rates per 100,000 for the United States were 28.8 in 1930, 26.5 in 1935, 22.5 in 1940, 19.9 in 1945, 16.0 in 1950, and 13.0 in 1955.)

2. A probable excess in the rates for certain foreign-born groups living in the United States over those of the native-born population.

3. An inverse relationship with socioeconomic status, with little evidence of specific occupational effects.

4. Great variation in stomach-cancer rates among countries.

5. Stable male-female ratios of rates for each country over the entire range of stomach-cancer rates.

6. Lack of marked urban-rural differentials.

7. The tendency for countries in northern latitudes to have higher rates, and the presence of north-south differences within the United States compatible with the broader international pattern.

Segmental Distribution of Cancer Within the Stomach

The location of the cancer in the stomach has a pertinent bearing on the operability and the choice of operative procedure. The lesser curvature has a special predilection for the site of gastric cancers, and the distal segment, namely, the pylorus and antrum, contains the majority of these new growths. However, they may occur in any portion of the stomach between the cardia and the pyloric ring. We have found an approximate frequency of involvement for the different segments of the stomach as illustrated in this table.

---

*Presented at the Postgraduate Symposium, University of Minnesota, May 17, 1963.

**From the Pack Medical Foundation, Inc., New York, New York.

TABLE I

	Our Series	L C H & C[18]
Pylorus and antrum	45%	70%
Pars media	25%	14%
Cardia or proximal segment	12%	13%
Greater curvature	6%	—
Total or diffuse	12%	—
Esophagogastric junction	—	13%

About 75 per cent of gastric cancers arise from the distal half of the stomach, and these are cured more frequently than those of the fundus or those that are diffuse.

Distribution of Metastases from Gastric Cancer

Patterns of Distribution

In approximately 11 per cent of the patients with gastric carcinoma, the initial physical examination will present clinical evidence of metastases to regions that permit an immediate prognosis of inoperability and incurability, e.g., the perirectal tissues (rectal shelf of Blumer), the signal node of Virchow-Troisier, the palpable nodular liver, diffuse lymphatic pulmonary carcinosis, ascites, the umbilical nodule, remote nodal metastases to such sites as the inguinal and femoral groups, and the Krukenberg tumor of the ovary.

Blood-Vessel Invasion

Meissner demonstrated blood-vessel invasion in 57 per cent of patients with gastric cancer. He was unable to prove any correlation between the extent of metastases to lymph nodes and blood-vessel invasion, and no apparent relationship to the gross or microscopic types of the primary cancer in the stomach.

Metastasis to Perigastric Lymph Nodes

Coller reported involvement of lymph nodes in 75 per cent of his patients. Microscopic examination of the nodes frequently revealed metastases that were not apparent on gross inspection. There was no correlation between the size of the nodes and the presence or absence of metastases in the nodes. In Coller's experience, the polypoid gastric cancers produced lymphatic metastases in 60 per cent of cases, and the diffuse or invading cancers in 95 per cent. In due course of time and with continued active growth of the cancer, the metastases extended far beyond the perigastric nodes to involve nodes in the hilus of the liver, the para-aortic nodes, etc.

Cancers involving the distal gastric segment, particularly of the prepyloric region and antrum and converging on the lesser curvature, metastasize to lymph nodes along the hepatic pedicle in about 40 per cent of the patients with gastric cancer.

The "second-look procedure" of Wangensteen and associates revealed a high incidence of metastases to lymph nodes in the region of the hepatic pedicle and the retropancreatic site. Arhelger disclosed that when these sites are dissected from their lymph nodes, the involvement of regional nodes from gastric cancer reaches the high incidence of 90 per cent.

Perisplenic lymph nodes were involved by carcinoma from the stomach in 20 per cent of 63 cases reported by Zdeněk and Dvořáček, who stress dissection en bloc of the lineal vessels and contiguous tissues, with splenectomy and extended gastrectomy.

Significance of Supraclavicular Signal Node

In 1848, Virchow described metastasis to the supraclavicular fossa in the presence of abdominal cancers. Troisier in 1849 published a study of 27 primary abdominal cancers, the majority in the stomach, which had metastasized to supraclavicular lymph nodes. The eponyms* of Virchow's and Troisier's node have found popular usage to this day.

Viacava and Pack found that 23 (2.6 per cent) of 883 patients with gastric carcinoma had obvious metastatic involvement of the signal node, and in 17 of the 23 patients the recognition of this abnormal node was the first evidence of the cancer. In fifteen patients the left supraclavicular node was involved; in three patients, the right node; and in five patients the metastases occurred bilaterally to the neck. The route of metastasis is along the various lymph vessels to the perigastric lymph nodes and the coronary, celiac, and superior mesenteric nodes. By way of the truncus intestinalis the cancer emboli enter the cisterna chyli, travel upward along the thoracic duct, and enter the systemic venous circulation at the left side of the base of the neck.

---

*See Test Your Word Score Page 763.

Metastasis to the signal nodes connotes a poor prognosis with no possibility of curative treatment. Biopsy of the left scalene node can reveal occult metastasis to the supraclavicular region and prevent needless exploratory laparotomy in selected instances.

Frequency of Various Symptoms

In approximately 0.5 per cent of the patients, there are no symptoms (asymptomatic or silent gastric cancer). Few significant differences exist in the frequency of each symptom with the exception of *dysphagia,* which occurred twice as often in patients with inoperable cancer as in those with resectable tumor. Dysphagia is more frequent in cancer of the cardia. Cancers in this location show a 20 per cent higher resectability because they apparently often manifest their presence early by dysphagia. Other symptoms are indicated in this table:

TABLE 2
Frequency of Symptoms

Weight loss	56-96%
Abdominal pain	22-96%
Vomiting	59-90%
Constipation	8-80%
Anorexia	17-82%
General indigestion	40-69%
Nausea	20-69%
Hematemesis	7-34%

The fact worthy of emphasis is that few significant differences in the incidence of various symptoms exist between patients with operable and those with inoperable gastric cancer.

The incidence of the first symptom experienced by the patient reveals no significant feature relative to operability.

Culpability for Delay in Diagnosis

Twenty years ago Pack and Gallo analyzed a large number of case records of cancer in an attempt to determine the responsibility for the delay in treatment. A delay of three months or more from the time of discovery of symptoms to the visit to the physician was regarded as undue delay on the part of the patient (Table 3). Criticism of the physician was based on the action taken by the first physician consulted. Leach and Robbins, using the same source material, showed improvement in the alertness of the patient but the same, or uncorrected, culpability on the part of the physician.

TABLE 3
Delay in Diagnosis

Due to patient	44.3%
Due to patient and Physician	18.0%
Due to physician alone	17.0%
No delay	20.7%

Relation of Gastric Ulcer to Gastric Cancer and Factors Influencing Treatment

In this controversial problem, there seem to be two important questions: (1) the diagnostic problem, which involves the clinical, gastroscopic, radiologic, and pathologic differentiation between gastric ulcer and ulcerocancer; and (2) the etiologic problem, involving the possible relationship of ulcer and ulcerocancer of the stomach, the consideration of precancerous lesions common to the two diseases, and the question of cancerous transformation of a benign gastric ulcer. First to distinguish between chronic ulcer and cancer of the stomach was Matthew Baillie of London who, in 1818, wrote his thesis on "The Morbid Anatomy of Some of the Most Important Parts of the Human Body."

The two accepted varieties of simple peptic ulcer are (1) the superficial type, which is not penetrative and is not to be confused with ulcerocancer, and (2) the deep, chronic peptic ulcer that does penetrate through the wall of the stomach and may simulate cancer in many aspects. The chronic gastric ulcer has steeply inclining walls with overhanging margins, and the circumferential mucosa is relatively normal. The two varieties of ulcerating cancer are (1) the ulceration of a fungating exophytic* cancer in which the ulceration is secondary and not usually mistaken for peptic ulcer, and (2) the penetrating or ulcerocancer, which is difficult to distinguish from the penetrating gastric ulcer.

Do Gastric Ulcers Become Malignant?

The histologic evidence of such conversion is too scanty to permit the assumption that gastric ulcer per se is a common precancerous lesion. There are few bona-fide cases in the experience of most surgeons and pathologists — just enough to admit of this possibility. The engrossing and practical question here is not concerned with the possibilities of secondary malignant degeneration of a chronic gastric ulcer (estimate, 5 per cent), but rather whether the ulcerating lesion in the stomach of a given patient is benign or malignant.

---

*See Test Your Word Score Page 763.

Age of the Patient

In patients more than 60 years old, one should suspect carcinoma more frequently than benign gastric ulcer. The percentage of ulcerating lesions that are malignant increases with age. Benign gastric ulcer is 15 to 20 times more common in the third decade of life than the ulcerating carcinoma. Comfort and Butsch of the Mayo Clinic found the relative incidence of benign gastric ulcer to be somewhat greater than that of ulcerating carcinoma in all decades except the eighth, but in the eighth decade ulcerating carcinoma was about twice as frequent as benign gastric ulcer.

Size of the Ulcer

Larger ulcers are more likely to be malignant than smaller ones, yet the very small ulcers are sometimes carcinomatous and the very large ones can be benign. Mandred Comfort has presented statistical evidence supporting his contention that the size of the ulcer does have statistical significance.

Location of the Ulcer

Ulcers on the greater curvature of the stomach are almost always malignant. There are occasional exceptions in which some on the greater curvature are benign; on the other hand, there are very few ulcerative lesions, of any type, situated on the greater curvature.

The higher up on the lesser curvature one goes toward the cardia, the higher is the proportion of malignant ulcers. The region of the incisura angularis is the most frequent site of benign ulcers. Holmes and Hampton, of Boston, many years ago stated that three fourths of the ulcers within one inch of the pylorus were malignant. Now it is believed that the incidence of ulcer and of ulcerocancer is about fifty-fifty in the immediate prepyloric region. On the lesser curvature, either benign ulcers or ulcerocancers can occur freely, so that one would never be safe in guessing the nature of any lesion along the lesser curvature no matter where it is, except, perhaps, in the region of the fundus.

Significance of Initial Hemorrhage

The incidence of massive hemorrhage is only about 6 per cent in patients with gastric cancer. Reports on hemorrhage from gastric ulcer relate a frequency of 20 to 40 per cent, or three to seven times as great as that noted among patients with gastric carcinoma.

Significance of Gastric Analysis

In distinguishing between the gastric ulcer that is benign and that in which carcinoma is found, one tends to diagnose benign ulcer in the presence of a higher gastric acidity. The volume concentration and output of acid in the nocturnal gastric secretions are lower in patients with gastric carcinoma than in normal healthy individuals, or in patients having either duodenal or benign gastric ulcer. Nevertheless, there are some carcinomatous ulcers associated with hyperchlorhydria, just as there are occasional benign ulcers accompanied by achlorhydria. One proper conclusion about this relationship is that any patient with achlorhydria and an ulcerating lesion in the stomach should be considered a candidate for surgery, because the odds are at least seven to one that he has gastric cancer (S.M. Jordan).

A review of patients for achlorhydria by Hitchcock, Sullivan, and Wangensteen yielded 1,747 patients with achlorhydria, of whom 19 were discovered to have gastric carcinoma; nine of these (47 per cent) were found to have metastases to regional lymph nodes at the time of operation. These cancers produced no symptoms.

Radiographic Comparisons of Benign Ulcer and Ulcerocancer

Certain possible sources of error in the X-ray diagnosis of benign gastric ulcer and ulcerocancer are (1) hypertrophy of the prepyloric muscle, (2) exaggeration of the mucosal folds with gastritis, and (3) obliteration of the mucosal folds in such a fashion that mucosal destruction by carcinoma is simulated. The margins of the ulcerocancer are usually nodular and irregular, whereas the margins of the benign ulcer are commonly symmetrical, clean-cut, and overhanging. In cancer the crater is within the lumen of the stomach; in benign ulcer it projects beyond the lumen. In ulcerating cancer, the mucosal folds may point to the crater but they do not reach it, terminating at a more or less broad, circumferential plateau of infiltrating cancer. Some of the ulcerocancers have a triangular shape. The more rigid the adjacent wall, the more likely it is that carcinoma rather than benign ulcer is present.

The typical ulcer of carcinoma is usually shallow and saucerlike with the width greater than the depth; per contra, the ratio of the depth to the width of the crater is commonly greater in benign ulcers. The ulcer floor in cancer may be nodular, whereas in benign ulcer it is usually smooth. At times, a fluid level may be demonstrated in the crater of the benign ulcer when the patient is erect, a detail that is not elicited in the case of ulcerocancer. The so-called meniscus sign was considered by Carman and Kirklin as the one sign that almost insured malignancy. Ross Golden has stated that the meniscus sign is produced by a crater in a mass; when pressure is applied, the mass pushes the barium away and leaves barium in the crater with a clear halo around it. Schumacher and Hampton have described a wide band of translucency owing to the overlying margins of the benign ulcer.

Roentgen-ray evidence of healing or diminution in the size of the lesion does not assure its benignancy, because carcinomatous ulcers can become smaller under conservative medical care, but they do not heal completely. The X-ray examination of the stomach under medical management of a supposedly benign ulcer must be repeated until complete disappearance is demonstrated, and there must not be residual rigidity in the gastric wall at the site of the previous ulcer. If the ulcer does not diminish in size under conservative medical care, this should be taken as strong evidence in favor of cancer, and surgical intervention should be recommended.

Gastroscopic Differentiation of Benign and Malignant Ulcers

A benign gastric ulcer usually appears through the gastroscopic ocular as having a clean base and smooth, sharp sides, sometimes with overhanging margins, whereas the malignant ulcer is commonly characterized by a necrotic or hemorrhagic base with irregular margins.

Excised "Benign" Ulcers Found to be Cancerous on Microscopic Study

What percentage of excised gastric ulcers, supposedly benign, are found to be cancerous on microscopic study? This chance of error is surprisingly uniform even in the experience of excellent diagnostic clinics (Table 4). Bille and Rømcke observed that cancer is missed three times as often in patients above 50 years of age as in those below this age, and that the incidence of misdiagnosed cases increases progressively with advancing years so far as males are concerned.

TABLE 4
"Benign" Gastric Ulcers Found to be Cancerous

Arthur Allen (Boston)	14.0%
Samuel F. Marshall (Lahey Clinic)	15.8%
Lampert, Waugh, Dockerty (Mayo Clinic)	13.0%
Ravdin and Horn (99 patients)	11.0%
Tien-Yu Lin (Taiwan Univ. Hosp.: 85 cases)	14.1%
Bille and Romcke (Norway: 908 cases)	2.9%

Therapeutic Tests

The response of the ulcer to a therapeutic trial of medical care is of aid in the differential diagnosis of ulcer from ulcerocancer. However, such management should be done with the patient in the hospital and with the understanding that if the ulcer does not heal and the healing is not progressive and complete, surgical excision is mandatory. Admittedly, ulcerocancer may be mistaken for gastric ulcer, but this error can be safely corrected if the patient is not continued unwisely on medical therapy for a time sufficient to be termed a dangerous delay.

Surgical Treatment of Gastric Ulcer

The patient with a small ulceration in the stomach, in our series of private patients, was considered to have gastric cancer until proved otherwise. In the Memorial Cancer Center, surgical treatment was recommended (by G.T.P.) to every patient with the exception of the following: (1) the youthful subject, under 35 years old, because the chance of cancer was less; (2) the aged subject, more than 70 years old, because of increased operative risk; (3) the debilitated subject, for any reason; (4) the patient with some other disease, the potentialities of which were as serious as the possibility of cancer; (5) the patient who refused surgery.

The ulcer should be removed so that its identity may be established by microscopic study. About 15 per cent of this group of patients are treated medically because of the previously mentioned contraindications to surgery; 70 per cent will undergo subtotal gastrectomy, and a few (5 per cent), total gastrectomy, usually because of an erroneous gross surgical diagnosis of cancer. The resectability rate for ulcerocancer varies from 90 to 95 per cent, with a mortality rate of 7 per cent. The absolute five-year survival rate for patients with carcinomatous ulcer averages 40 per cent. Thirty per cent of patients with gastric cancer who survived five years or longer at the Buffalo General Hospital had cancer which developed in a chronic peptic ulcer (Lipp and Phillips).

An operative mortality of 7 per cent, compared with the hazard of ulcerocancer existing in 29 per cent of patients preoperatively considered to have benign gastric ulcers, would fortify the opinion that the operation is less dangerous than medical treatment. Other surgeons are less inclined to adopt routine surgical therapy. Samuel F. Marshall, for example, contends that only 50 per cent of chronic gastric ulcers require operation. Finally, the reported experience of Welch and Burke may be cited: Of 367 patients with apparently benign gastric ulcers seen at the Massachusetts General Hospital during the years 1952 through 1957, 221 (60.2 per cent) underwent surgery, with a mortality of 3.6 per cent. The postoperative mortality in 47 patients with acute massive hemorrhage or severe grades of anemia was 10.6 per cent, and in the 174 without hemorrhage, 1.7 per cent. Of these patients, 16 (7.2 per cent) had cancer.

The Surgical Treatment of Gastric Cancer

Radical Subtotal Gastrectomy

This procedure remains the standard operation for the treatment of the majority of gastric cancers confined to the distal segment of the stomach. Carcinomas of the antrum or of the posterior wall of the pars media, and the small, ulcerating lesions of the lower lesser curvature are readily resectable by this operation, always in combination with perigastric lymph node dissection and omentectomy.

The salient features of the radical subtotal gastrectomy for carcinoma of the distal gastric segment are as follows:

1. Dissection of all fat, areolar tissue, and lymphoid tissue from the hepatic triad and portal fissure proximally, to include the entire gastrohepatic omentum.
2. Dissection of the gastrocolic and great omenta.
3. Ligation and severance of the right gastric and right gastroepiploic blood vessels.
4. Low transection of the duodenum.
5. Ligation of the left gastric artery at its origin with the celiac axis and dissection of the lymph nodes in the celiac group.
6. High proximal resection of the stomach.
7. Distal pancreatectomy and splenectomy for those cancers of the distal segment that extend appreciably into the pars media, especially along the lesser curvature.
8. Restoration of gastrointestinal continuity by gastroduodenostomy or by gastrojejunostomy.

For the restoration of gastrointestinal continuity after subtotal gastrectomy, the Billroth II principle of repair is preferred over the Billroth I plan of anastomosis.

Transthoracic Esophagogastrectomy

A transthoracic esophagogastrectomy is the generally accepted procedure of choice for cancers of the proximal third of the stomach. The employment of the laparothoracotomy incision and the adequate exposure it affords have produced a dramatic change in the operability of cancers of the proximal gastric segment during the past two decades.

The Extended Total Gastrectomy for Cancer

Total gastrectomy alone is not an adequate operation for cancers requiring removal of the entire stomach, as it does not remove the field of lymphatic spread with the stomach. The extended total gastrectomy based on the anatomic studies of lymphatic spread is the procedure advocated by the authors. It implies complete gastrectomy, partial distal pancreatectomy, splenectomy, dissection of the gastrocolic and gastrohepatic omenta as well as the areolar and lymphatic tissues extending over the hepatic triad to the portal fissure, and clearing of the celiac axis.

Indications for total gastrectomy include: (1) the average carcinomas of the proximal and middle thirds of the stomach, owing to the distribution of the lymphatic spread; (2) carcinomas of such a size and location that they cannot be completely removed by subtotal resection of either the distal or proximal segments of the stomach; (3) carcinomas of the diffusely invasive type; (4) linitis plastica (cancer); (5) all superficial spreading mucosal cancers; (6) carcinomas of the distal segment invading high along the lesser curvature or into the pars media.

Methods of Restoring Gastrointestinal Continuity after Total Gastrectomy. These include:

1. Esophagoduodenostomy (direct)
2. Jejunal interposition between esophagus and duodenum
   a. Method of Longmire and Beal
   b. Method of Claude J. Hunt
3. Esophagojejunostomy
   a. Simple terminolateral anastomosis of the esophagus to jejunal loop either with or without a Braun supplementary enteroenterostomy
   b. Roux en-Y anastomosis
   c. Method of Day and Cunha
   d. Method of Lima-Basto
4. Interposition of transverse colon between esophagus and duodenum
5. Interposition of ilecolon (right) between esophagus and duodenum

Operability and Resectability: Operative Mortality

Lippo and Phillips, in a total of 12,728 patients (18 series) with gastric cancer culled from the literature between 1947 and 1955, reported an operability rate of 70.5 per cent and a resectability rate of 34 per cent; the operative mortality was 15 per cent. An operability rate of 82 per cent and a resectability rate of 49 per cent were reported from the Charity Hospital in New Orleans by Lumpkin, Crow, Hernandez, and Cohn. Of a series of 1,623 patients observed in 1931 through 1955 at the Memorial Hospital, New York City, 1,315 (81 per cent) were submitted to some form of operation; 197 patients (15 per cent) died in the hospital as a direct result of surgery (McNeer, Lawrence, Ashley, and Pack).

A progressive improvement in operability and resectability with increase in age from 30 to 80 years is usually observed. The resectability rate is approximately the same for both sexes.

Prognosis and End Results

Duration of Life in Untreated Gastric Cancer

For the average patient with cancer of the stomach, death occurs within less than one year from the onset of the first symptom or sign, when no treatment is employed. The remaining fragment of life for the average patient, from the time of hospital admission until death is less than four months. As a general rule, all patients with untreated gastric cancer are dead within one and a half years from the time of hospital admission, and not over 3 per cent of these are alive at the end of a year after seeking institutional care.

Operable but Incurable Patients

For those patients who undergo exploratory operations and are found to be incurable, the outlook is much the same as for patients with inoperable cancer, unless the local tumor is resected. Unusual are two patients reported by Lipp and Phillips from the literature who, on exploratory laparotomy, were declared inoperable and who survived five years. Palliative gastric resection may account for prolongation of life in some patients. Patients subjected to nonresectional operations (bypass operations) have survival rates very similar to those of the groups who are inoperable.

Gastrectomy for palliation, as reported from Denmark by Zacho and Fischermann, is seldom, if ever, indicated. A higher mortality occurs, and the accomplishments seldom warrant the procedure. Hoerr and Hodgman aptly state that the best results from palliative gastrectomy occur when the surgeon believes he is performing an operation for cure. Conversely, 22 of 47 patients who survived five years in the Charity Hospital of New Orleans series had what the operating surgeons believed were palliative resections.

Patients Who Have Curative Operations

About 25 per cent of these patients will be alive at five years and of these, approximately 10 per cent will succumb from their cancer after the five-year mark (McNeer, Lawrence, Ashley, and Pack). Most of the therapeutic failures occur within the first three or four years following curative resection. A large proportion of patients who have undergone curative resection for gastric cancer may, therefore, anticipate cure if they have survived this period. The five-year yardstick for the estimation of "cure" would seem to be a practical measurement in assessing the end results for gastric cancer.

Factors Influencing the Prognosis

Various factors influence the prognosis: (1) The symptomatology. Patients with the ulcer syndrome have the highest percentage of cures. (2) The location of the cancer. Patients whose cancers are located in the distal segment of the stomach are cured more frequently than those with tumors in the proximal segment. (3) The gross characteristics of the tumor. Polypoid and ulcerating cancers have a higher cure rate (approximately 45 per cent) than infiltrating cancers (10 to 15 per cent). (4) The degree of differentiation. Grade I cancers have a five-year cure rate of 66 per cent; Grade II, of 40 per cent; Grade III, of 24 per cent; Grade IV, of 12 per cent. (5) Metastasis to lymph nodes. Twelve to 15 per cent of patients with metastasis to lymph nodes proved microscopically are cured in contrast to 40 per cent of those who have no evidence of lymph node metastasis.

To date, surgery has been the only means of curing or controlling gastric carcinoma. Radiation therapy and chemotherapy, as surgical adjuncts and as palliative agents, have been disappointing. Approximately 20 per cent of patients have demonstrated some palliation from megavoltage irradiation but no significantly increased longevity.

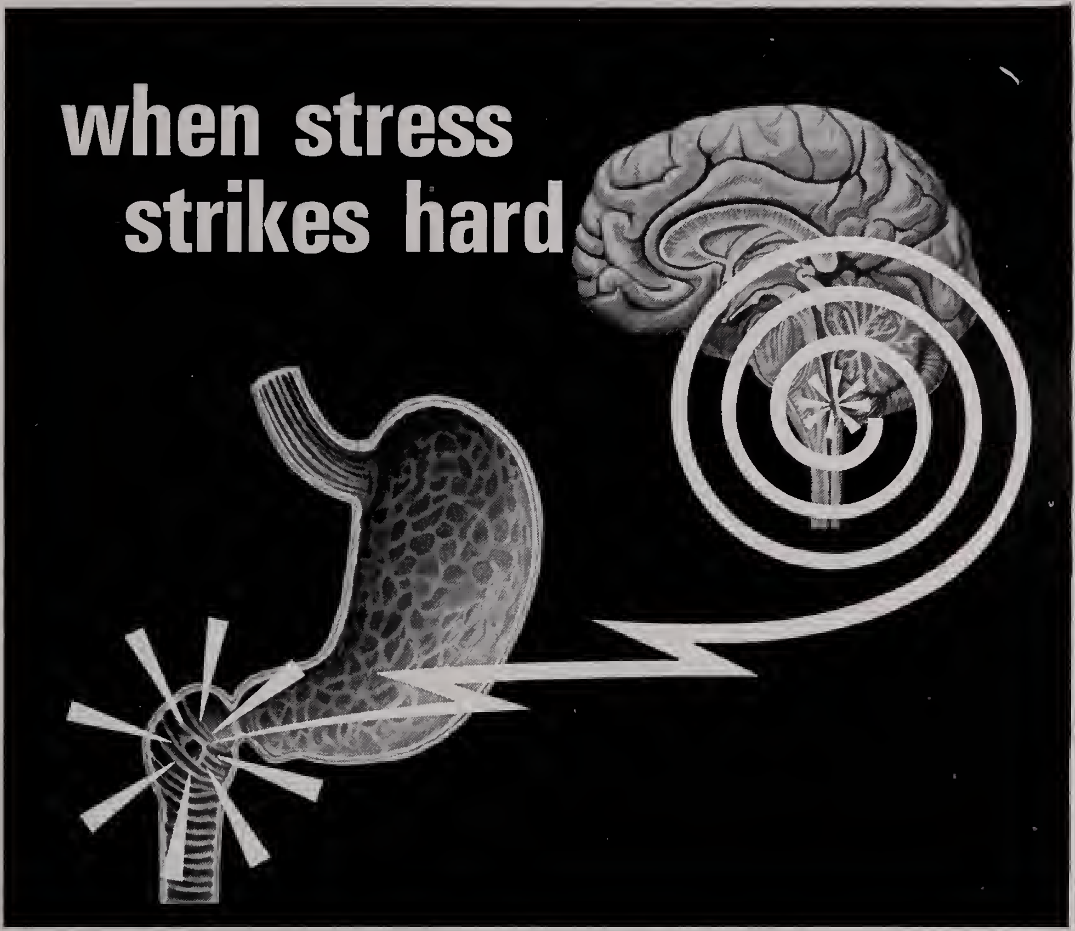
Salus

In the Roman hierarchy of divinities Salus was the goddess of health, corresponding to the Greek goddess Hygeia. Hence the derivative greeting, Salutations! (Your health!)

Retirement without the love of letters is a living burial. — Seneca



PRO-BANTHĪNE® *with* DARTAL®

Each tablet contains: propantheline bromide (15 mg.) and thiopropazate dihydrochloride (5 mg.)

controls autonomic imbalance

Peptic Ulcer • Pylorospasm • Irritable Colon • Functional Gastrointestinal Disorders

Firm control of both the psychic and visceral disturbances is indicated when emotional stress adversely influences gastrointestinal disorders. Pro-Banthīne with Dartal has demonstrated its ability to provide such control.

Pro-Banthīne, as expected, reliably moderates excesses of gastric secretion and gastrointestinal motility.

Dartal, a dependable, well-tolerated tranquilizer, calms the emotional turbulence that aggravates enteric disturbances.

Together, Pro-Banthīne with Dartal offers twofold therapeutic access to a twofold clinical problem.

Urinary hesitancy, xerostomia, mydriasis and, theoretically, a curare-like action may occur with Pro-Banthīne (propantheline bromide) and it is contraindicated in the presence of glaucoma or severe cardiac disease.

With Dartal (thiopropazate dihydrochloride) extrapyramidal and parasympatholytic symptoms have been reported and, rarely, leukopenia, erythematous skin reaction and allergic purpura. Do not administer to patients under the influence of alcohol, barbiturates or narcotics and use cautiously with sedatives, in epileptic or depressed patients or in those with liver damage. Reactions typical of phenothiazines may occur.

Dosage: One tablet three times a day.

Prevention of Potassium Wasting

Potassium deficiency occurs commonly, and, for that portion of it secondary to diuretic therapy, the physician accepts responsibility. Elsewhere in this issue Snively* reviews concisely the matter of potassium "defect," including its prevention during thiazide therapy with a daily supplement of potassium. The logic, of course, is that renal wasting of potassium, inherent in the action of all thiazides, is the cause of the potassium deficit. Deficits of potassium secondary to thiazide therapy, however, are also accompanied by deficits of chloride and hydrogen ions, and this triad cannot be entirely prevented or completely repaired by potassium salts.

The studies of Sandoe and Olesen[1] illustrate the problems involved in the prevention of potassium deficiency during chronic thiazide therapy. During one month of thiazide therapy, patients in congestive heart failure regularly had hypokalemia (39 per cent of 18 patients), metabolic alkalosis (50 per cent), and hypochloremia (77 per cent). Renal losses were responsible, and balance studies defined the magnitude of the deficits. Prevention of these losses proved to be difficult and incomplete by the daily use of 3 Gm. (43 mEq.) potassium chloride or 400 mg. spironolactone. When potassium chloride was given, hypokalemia still developed in 11 per cent and alkalosis and hypochloremia in 39 per cent. When spironolactone was given, hypokalemia was not observed, but alkalosis was present in 10 per cent, hypochloremia in 68 per cent, and hyponatremia in 23 per cent.

Combined therapy using potassium and spironolactone has been advocated[2] during thiazide administration for patients with fluid retention due to portal cirrhosis, the nephrotic syndrome, or malignant hypertension.

In these conditions, the production of aldosterone is greatly increased, exaggerating the trend toward deficits of potassium. In congestive heart failure, aldosterone production is not as great, and combined therapy can be reserved for patients with refractory edema. Hyperkalemia with hyponatremia may result from therapy with spironolactone and thiazides.

The prevention of potassium deficiency during diuretic administration may not be a simple matter, and it remains a goal of proper therapy.

to help relieve pain
in common
anorectal disorders

"non-caine"
Diothane®

Diothane—with its chemically distinct "non-caine" anesthetic agent diperodon—provides effective temporary topical anesthetic and emollient actions for soothing relief of anorectal pain. Anesthetic activity is effective and relatively prolonged; sensitization is infrequent. Reports to Merrell on 1,500 patients treated pre- and postoperatively with Diothane Ointment, indicate only 22 developed local skin reactions. Reactions to Diothane have been burning or stinging sensations and a few cases of allergic manifestations. An additional advantage: Diothane Ointment and Suppositories are mildly antiseptic. Prescribe or recommend either form . . . both are now available.

DIOTHANE OINTMENT

COMPOSITION:
diperodon 1.0%; oxyquinoline benzoate 0.1% in a special ointment base.

INDICATIONS:
Provides temporary palliation of pain that may result from hemorrhoidectomy and from common anorectal disorders such as hemorrhoids, anal fissures, pruritus ani.

DIOTHANE®
OINTMENT
PULL APART

DIOTHANE SUPPOSITORIES

COMPOSITION:
Each suppository, weighing approximately 2.6 Gm., contains diperodon 1.0%; urea 10.0%; oxyquinoline benzoate 0.1% in a special hydrophilic suppository base. A unique shape keeps the suppository in intimate contact with mucous membranes.

INDICATIONS:
Provide for temporary palliation of pain caused by hemorrhoids and pruritus ani.

Special Anatomy of Carpal Tunnel Syndrome

PRESSURE ON the median nerve causing motor and sensory deficit in the hand has been reported to occur most commonly at two levels. Occasionally the nerve becomes compressed as it passes through the two heads of the pronator teres muscle at the elbow. More frequently the compromise is at the wrist where the nerve courses beneath the flexor retinaculum. This produces the so-called "Carpal Tunnel Syndrome," reviewed in the study of Doctors Yamaguchi, Lipscomb and Soule in the January issue.* There are few groups that can marshall 1215 patients with this entity for review.

The anatomy of this lesion is of paramount** importance. Every surgical decompression of the carpal tunnel is a lesson in this anatomy. Carpal tunnel syndrome is primarily a problem of disproportion. The rigid walled canal is too small, or its contents too large to allow their comfortable passage. The structure which bellows its distress most vehemently is the median nerve. It is a median neuropathy which usually brings the patient to the physician. Seldom do the other contents of the canal become symptomatic.

The canal itself is an inflexible passageway. Dorsally it is bounded by the concave arch of the eight carpal bones, which are in turn covered by the radiocarpal, intercarpal and carpometacarpal ligaments. The volar roof of the canal is the transverse carpal ligament (flexor retinaculum). This ligament is firmly attached to four bony prominences, the pisiform and hook of the hamate on the ulnar aspect of the wrist, and the tuberosity of the scaphoid and the crest of the greater multangular radially. Ten structures of importance pass through the carpal tunnel to the hand. They include the four flexor digitorum profundus tendons, the four flexor digitorum sublimis tendons, the tendon of the flexor pollicis longus and the median nerve. Symptomatic compression of the latter causes the paresthesias, pain, atrophy and weakness so typical of this syndrome.

The wrist flexors, the radial and ulnar arteries and the ulnar nerve do not pass through the carpal tunnel. The radial portion of the flexor retinaculum splits into two layers to provide a separate compartment for the flexor carpi radialis tendon. Likewise on the opposite side of the wrist the ulnar nerve and artery pass superficial to the transverse carpal ligament through their own tunnel, the canal of Guyon. None of these structures are involved in carpal tunnel syndrome.

The symptoms of carpal tunnel syndrome usually subside in a most gratifying manner when the compression is surgically relieved.

Radiological Evaluation of the Hypertensive Patient

RENOVASCULAR CAUSES with curable lesions are conservatively estimated to be present in 2 to 5% of all cases with hypertension. The prevalence of hypertension in the community today is so extensive that a meager percentage represents approximately 5% of the adult population in the United States. Persistent diastolic hypertension, progressive or untreated in the majority of instances, shortens the life span of the victims. Since hypertension of renal origin may be correctable by the use of contemporary surgical technique, whether by vascular reconstruction or nephrectomy, it is essential to evaluate hypertensive patients with currently available diagnostic procedures.

Numerous special diagnostic procedures and observations on "routine" examinations have been developed over recent years. Much experience and sophistication has followed in performing and interpreting intravenous

pyelography, arteriography, split renal function studies, and radioisotope techniques.

Arteriography is necessary prior to surgery to observe the number and position of the renal arteries. This procedure remains the single most direct means for exclusion of a possibly significant renal artery lesion. A "significant" narrowing does not necessarily mean that surgically "curable" renovascular hypertension exists. In fact, a narrowed artery is not an uncommon finding in our cases that have aortograms for various other reasons. A number of patients have been operated on at the University of Minnesota Hospitals with 50 to 70% narrowing as estimated on angiograms and subsequently confirmed at surgery without relief of hypertension or its symptoms.

Considerable strides have been made in the evaluation of the data obtained from the radioactive renogram. The introduction of Hippuran® has increased the usefulness of this screening procedure greatly. Although in the classical case a fairly typical pattern of unilateral renovascular disease has emerged, there still remains a considerable number of renograms that are nonspecifically abnormal. Additional studies are required for evaluation in these cases. Rarely is the renogram completely normal in the presence of a significant lesion.

Characteristic changes observed on "routine" intravenous pyelography in the past have been infrequently observed in the curable cases. Differences in nephrographic phase and kidney size are poorly appreciated except in the severe cases. Possibly, the measurement of kidney perimeters as recommended by Eelkema in a recent issue of Minnesota Medicine* may improve the percentages.

A recent modification in the intravenous pyelogram, namely, the introduction of a large bolus with rapid sequence films, has remarkably improved the study as a screening agent. Disparity in the nephrogram becomes more evident, and additional parameters such as time of appearance, relative concentration, and clearance of dye from the upper collecting systems are made available. The use of various diuretic agents has further increased the number of diagnosed cases.

Surgically-amenable, renovascular hypertension has been discovered in the old as well as the young. Some patients have had hypertension of long standing prior to diagnosis and have improved remarkably following surgical intervention.

Emphasis therefore must be placed on full evaluation of any hypertensive patient for curable causes, despite age or duration of disease process. What should this evaluation entail? Currently at the University of Minnesota and with slight modification at the Minneapolis Veterans Administration Hospital, the patient referred to the Radiology Department for intravenous pyelography because of "hypertension" undergoes the following studies. A renogram is performed in the dehydrated state, followed by intravenous pyelography employing a combined fast injection and urea-washout technique.

When combined with renogram, the modified intravenous pyelogram will provide an adequate screening test in the majority of cases to determine where further more elaborate techniques, such as split renal function test and/or renal arteriography, are indicated. Much remains to be learned about the factors leading to renovascular hypertension with the basic understanding that it is not always dependent on renal ischemia but may be on the basis of pressure-flow differences between the aorta and the renovascular bed.

Man is only man at the surface. Remove his skin, dissect, and immediately you come to machinery. — Valery

New broad-spectrum penicillin but without broad-spectrum toxicity[1-10]

no blood dyscrasias
no photosensitivity
no severe gastric disturbances
no pigmentation of teeth
no kidney damage
no accumulation in long bones

PENBRITIN (ampicillin) brings the traditional penicillin advantages to areas of treatment formerly dominated by the tetracyclines and chloramphenicol – urinary and gastrointestinal infections, as well as respiratory infections. But PENBRITIN (ampicillin) *does not cause the toxic disorders* associated with other broad-spectrum antibiotics.[1-10] And highly important: PENBRITIN (ampicillin) *kills* bacteria instead of merely suppressing them.

Usual dosage: Adults – 250 mg. every six hours in respiratory infections; 500 mg. every six hours in urinary and gastrointestinal infections (higher doses may be needed in severe infections). Children – (under 13 years, whose weight will not result in a dosage higher than that recommended for adults) 100 mg./Kg./day in divided doses every six or eight hours for moderately severe infections; 200 mg./Kg./day in divided doses every six hours for severe infections.

Contraindications: (1) Hypersensitivity to penicillin. (2) Infections by penicillinase-producing staphylococci and other penicillinase-producing organisms.

Side Effects: Mild effects, such as skin rashes, diarrhea, nausea and vomiting have occasionally appeared.

Precautions: As with other antibiotics, precautions should be taken against gastrointestinal superinfection. To date, safety for use in pregnancy has not been established.

Supplied: No. 606 – Each capsule contains 250 mg. of ampicillin. Bottles of 16 and 100.

Letter to the Editor:

I thought you might be interested in an incident which occurred Sunday at the meeting of the Policy Committee of the United States Chamber of Commerce. I have been a member of the Policy Committee for the past four years and have now taken my place as a member of the Board of Directors of the Chamber.

The doctors were well represented, especially by a group from Illinois, and they presented such a strong case against compulsory inclusion under Social Security, that I supported them in the Committee. However, the Committee concluded that Social Security was primarily a tax that should apply to everyone.

I still think it is inequitable for doctors who retire at an average age of seventy-two and would receive so little benefit from their contributions. The other members felt that Social Security is inequitable for lots of other people, so that doctors were included in the Policy Declaration, with only my vote in the negative.

Walter L. Rice
Vice President, Reynolds Metals

Editor's Note: It's been a long tussle, but I guess we have lost. It is interesting to know, however, paradoxical though it may be, that there is one businessman and 207,000 doctors who still believe that the economical security of the people depends on the labor and savings of individuals; that the State cannot be the entity by which everyone lives at the expense of everyone else without exerting one's self.*

P.S. Incidentally that businessman happens to be the editor's brother.

You've Made Us Change

APACHE MEDICAL COMPLEX

We started with plans for the most modern, most efficient, most tenant-oriented *medium-sized* medical complex in Minnesota. Your response forced us to change our plans. Now we're going to construct the most modern, most efficient, most tenant-oriented *large-sized* medical complex in Minnesota, to be built at Apache Plaza in two medium-sized stages. Stage 1, pictured above, will be ready for you in Spring, 1966.

Here are some of the reasons why Apache Medical Complex will be the ideal location for your new office:

- Ample free parking for everyone, reserved parking for doctors.
- Convenient for patients and staff, part of a 60-store shopping complex.
- Handy to Twin Cities hospitals.
- Attractive, dignified building, giving you the best professional address north of either loop.
- Complete facilities, including pathology and radiology laboratories.
- Essential ancillary services and shops.
- Restaurant facilities conveniently located for doctors, patients and staff.
- Modern building techniques will give total flexibility to your office space-planning.

The Editor's Soliloquy

Your Physiologic Age

The 50 Club

In the natural order of events, life proceeds uniformly from birth to death over an anticipated span of 71 years, a chronological period which cannot be greatly altered on the earth's surface. Astronaut scientists speculate that life processes can be slowed up almost immeasurably if man can be made to glide rapidly through space at the speed of light. Thus propelled, the physiological organism would presumably function so differently that human flesh, blood, and bone could survive for thousands of chronological years without aging more than a few physiologic years, but who among us wants to stay youthful that way?

Everywhere around us we see men and women old, worn, and exhausted at 40; less often we see men and women of 60 with young eyes, young bodies, and young voices belying their chronological age. Some men anticipate the indolence and apathy of retirement at 50; others decline to be put on the shelf at 65. Such are the members of our 50 Club.

A look at the lives of those who are physiologically older than their chronological age usually reveals a pattern of bad habits and excesses; ungoverned dissipation, undisciplined exertion, uncontrolled emotions. In such individuals the complex organism with its intricate balance is forced beyond its capacity to adjust. The body rebels and health abdicates. Cumulative deterioration results; old age sets in; senility arrives prematurely.

The end result is all too apparent on all economic levels, from Skid Row with its derelicts to the more affluent, bourgeois members of the Jersey Cow Key Club, on up to the elected and select habitues of the exclusive Country Club. Retribution does not operate on a caste system.

One of the greatest contributions of the ancient to the modern world was the Greek ideal of moderation in all things. In championing the virtues of maturity, Rostand* has pointed out that "if we leave on one side the great achievement and the splendid discoveries we owe to old men, we must ignore those precious and quiet irreplaceable accumulations of wisdom, doubt, and incredulity that Time lays down in the spirits of those who have been proved worthy to survive to venerable old age."

You physiologically young members of the 50 Club have been wise. You have observed nature's laws and are now in the enviable position of enjoying compound interest on your wise health investment. Salutations!

Carl O. Rice, M.D.

Regroton®

Superior to other antihypertensives in 76 of 80 patients in a 2-year study*

Geigy

mposition: Each tablet contains chlorthalidone,
mg., and reserpine, 0.25 mg.
ntraindications: History of mental depression,
persensitivity, and most cases of severe renal
hepatic diseases.
arning: Discontinue 2 weeks before general
esthesia, 1 week before electroshock therapy,
d if depression or peptic ulcer occurs.
ecautions: Reduce dosage of concomitant anti-
pertensive agents by one-half. Discontinue if
BUN rises or liver dysfunction is aggravated.
ectrolyte imbalance and potassium depletion
ay occur; take particular care in cirrhosis or
severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use with caution in patients with ulcerative colitis, gallstones, or bronchial asthma.
Side Effects: Nausea, vomiting, diarrhea, muscle cramps, headaches and dizziness. Potential side effects include angina pectoris, anxiety, depression, drowsiness, hyperglycemia, hyperuricemia, lassitude, leukopenia, nasal stuffiness, nightmare, purpura, urticaria, and weakness.
For full details, see the complete prescribing information.

Average Dosage: One tablet daily with breakfast.
Availability: Bottles of 100 and 1000 tablets.

*Chupkovich, V.; Finnerty, F. A., Jr., and Kakaviatos, N.: The value of chlorthalidone plus reserpine in moderately severe and severe hypertension: A two year study. Presented at the 7th Inter-American Congress of Cardiology, Montreal, June 14–19, 1964.

Fifty Years of Honorable Service in Minnesota

The presentation of certificates and pins to Minnesota physicians who have engaged in the practice of medicine for 50 years has become an impressive highlight of each Annual Meeting. According to custom the presentations are made during the course of the Annual Banquet. Few who have witnessed these ceremonies soon forget the setting of such an occasion at which these colleagues with a half century of medical practice to their credit so alertly respond to the roll call.

The custom of honoring Minnesota physicians who have served their patients and communities for a half century was established in 1942. Forty-one physicians were honored at the first ceremony. This group also included those who have passed the 50-year mark prior to 1942.

To be eligible for this award a doctor must have spent the majority of his 50 years practicing medicine in Minnesota.

In 1965 eighteen doctors were added to the membership rolls of the Fifty Year Club.

Arthur I. Arneson, M.D.

Dr. Arneson was born on February 7, 1892, to Axel and Brita Arneson, on a farm near Emmons, Minnesota. After his preliminary education, he entered the State University of Iowa, from which he graduated.

In 1917, he served in the United States Army Medical Reserve Corps, thereafter entering general practice in Morris, Minnesota until 1960.

He then took some special training in anesthesiology and since 1960 has limited his practice to anesthesia in the local hospitals in Minnewaska and Starbuck, where he works each morning. In the afternoon he carries on a practice of limited ophthalmology.

Dr. Arneson was an expert rifleman at the University of Iowa Rifle Team and has continued this hobby throughout his life. In addition, he is an enthusiastic fisherman, photographer, lapidarist, and during many of his holidays he searches for semiprecious stones. He is a conservationist and an active participant in outdoor recreation.

He is a member of the local Board of Education and a Director of the Lakeland Mental Health Center at Fergus Falls.

Dr. Arneson married Karine Emmons in 1916 and they have two daughters, both of whom have entered the medical profession as nurses. He has eight grandchildren. Like many physicians, Dr. Arneson has found it impossible to retire from the active practice of medicine.

Dr. Buie, Sr., M.D., A.B., D.Sc., Member Emeritus of the staff of the Mayo Clinic and of the faculty of the University of Minnesota; Diplomate of the American Board of Surgery; member of the House of Delegates of the American Medical Association, 1941 to 1955; member of A.M.A. Judicial Council, 1945 to 1960; Chairman of A.M.A. Council on Constitution and Bylaws, 1951 to 1957. While Chairman of this Council, he was largely responsible for writing the present *Principles of Medical Ethics* of the American Medical Association.

Dr. Buie came to Rochester, Minnesota, February 1917, as a Fellow in Surgery of the Mayo Foundation.

In 1919 he was appointed a member of the staff of the Mayo Clinic. At the suggestion of Dr. W. J. Mayo he organized the Section of Proctology at the Mayo Clinic and served as head of that section from 1919 until 1953, when he became senior consultant. He is Professor Emeritus in the Mayo Foundation Graduate School, University of Minnesota.

Louis A. Buie, Sr., M.D.

Dr. Buie was one of the founders of the American Board of Proctology in 1934, which he also served as secretary and president. He was certified by the American Board of Surgery in 1944. He served as president of the American Proctologic Society in 1927 and 1928 and again in 1934 and 1935. He was president of the Minnesota State Medical Association in 1947 and chairman of the Section on Gastroenterology and Proctology of the A.M.A. in 1947. He was president of the Zumbro Valley Medical Society in 1943 and 1944. He was a member and vice-chairman of the General Advisory Council of the National Foundation for Infantile Paralysis from 1949 to 1960. In July 1955 he was appointed a national consultant to the Surgeon General of the United States Air Force.

Currently Dr. Buie is Secretary-Treasurer of the Advisory Board for Medical Specialties and has served in this capacity since 1958. He has been Editor of *Diseases of the Colon & Rectum* since 1957. He is the author of several books and numerous original articles on diseases of the colon and rectum.

He is a Fellow of the American College of Surgeons and a member of Phi Beta Kappa, Society of Sigma Xi, and Nu Sigma Nu medical fraternity. In 1934 the Government of Italy conferred on Dr. Buie the Cross of Military Merit, and in 1949 the University of South Carolina awarded him the honorary degree of Doctor of Science.

Harry B. Clark, M.D.

Dr. Clark was born in St. Cloud in 1890 and for most of his active years in medical practice has carried on his profession in that city.

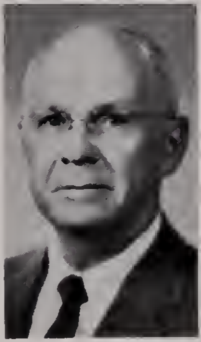
He attended Carleton College, after which he entered the University of Minnesota School of Medicine and spent his internship at the University Hospitals. He was married to Mabel E. Lundgren.

For a short period of time he carried on a practice in Clear Lake, Minnesota, but most of his time has been spent in St. Cloud.

He is on the staff of the Veterans Administration Hospital. He has served on the St. Cloud school board for eighteen years and is a director for the State College Board. He also served in the capacity of president of the State School Board Association.

He has two sons and three grandchildren, who are always eager to listen to his fascinating experiences. He carries on an active general practice.

Dr. Clark served in the First World War, the Second World War and the Korean War as a Medical Officer.



Lloyd T. Davis, M.D.

Dr. Davis is one among a long list of medical doctors. In his home town he is known as Dr. Tom, the youngest son of Dr. A. M. Davis, who has been mentioned in the early history of Wright County as a physician in Howard Lake and who, after practicing a total of fifty years in several localities, died in 1923.

Dr. Lloyd Thomas Davis came to Wadena in 1916 and practiced with his oldest brother, Dr. Luther A. Davis, until 1917, when he entered the United States Army Medical Corps in the first World War and served with the American Expeditionary Force in France. After his brother Luther died in 1920, Dr. Tom was joined by his next older brother, Thayer C. Davis, and the partnership continued until Dr. Thayer's death in 1949.

In 1940, a nephew, Luther F. Davis, joined the group, and in 1946 a son was added to the group, and they practiced together in Wadena until 1954.

Another son, Dr. William G. Davis, has practiced in Hawaii for seven years but is presently a resident in urology in Denver.

Dr. Davis was married in 1918 to Phyllis Dower of Wadena. In addition to the two doctor sons, as mentioned above, they had a son, Michael, a daughter, Denise (Mrs. A. W. Ferron), and a daughter, Judith (Mrs. H. W. Oehler).

Dr. Davis removes himself from the vigors of Minnesota winters, but he returns to Wadena in the middle of April, serving his community largely in the capacity of consultant.

Frank J. Elias, M.D.

Dr. Elias was born on July 1, 1892, in Racine, Wisconsin, where he spent his early days.

He entered Marquette University School of Medicine and graduated with an M.D. degree in 1914. He served his internship in the St. Mary's Hospital in Duluth and thereafter was associated with W. H. Magie, M.D.

In the First World War, he was with the American Expeditionary Force and also served in the British Expeditionary Force.

Dr. Elias, in addition to being a member of the local and state societies, is a Fellow of the American College of Surgeons and served as president of the Minnesota State Medical Society in 1950. He was also president of the St. Louis County Medical Society and one of the Minnesota delegates to the American Medical Association.

He belongs to the Rotary Club and the Royal Order of Jesters, and he was in a partnership group of the Morgan Park Medical Center in Duluth from 1919 to the present date. He was a surgeon with U. S. Steel and the Oliver Iron Mining Company of Duluth.

In 1954 he received the Distinguished Service Medal for his numerous contributions to the welfare of our state medical organization.

He was Chief of Staff of St. Mary's Hospital and president of the Interurban Medical Society in Duluth. His hobbies are greenhouse projects and tape recording.

Continued

Frederick W. Franchere, M.D

Dr. Franchere was born on October 24, 1889, in Lake Crystal, Minnesota, from a third generation Blue Earth County resident. After attending the local schools, he entered the University of Minnesota for two years, then transferred to Marquette University Medical School and graduated in June 1915. He passed State Board examinations in Wisconsin and served a six-month internship in the Milwaukee Children's Free Hospital and a six-month internship in the Lying In Hospital in Chicago.

He then returned to Minnesota and passed the Minnesota State Board examination in 1916. Thereafter he entered the private practice of medicine in Lake Crystal, but at the time of the first World War he joined the American Expeditionary Force and served as a first lieutenant in the Medical Corps in France.

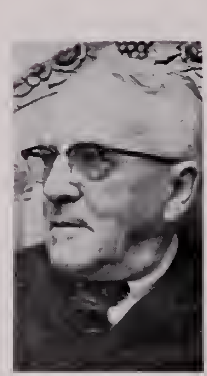
Upon his return he continued to practice in Lake Crystal up to the present date.

He was married to Amanda Larson, a coed at the University of Minnesota, on August 6, 1919. They have two daughters, Mrs. Nilla Franchere Osten of St. Paul, and Helena Franchere Slind of Mt. Prospect, Illinois.

Dr. Franchere is a member of the Zion Lutheran church, Masonic Lodge, American Legion, the Blue Earth County Medical Society and the Minnesota State Medical Society. He is a life member of the International Postgraduate Medical Assembly.

Dr. Halloran was born in Farmon, North Dakota, on August 4, 1889, the son of F. J. and Nell Tracy Halloran. Dr. Halloran's parents were of pioneer Minnesota families. His father practiced medicine in Chatfield and St. Paul for many years.

Dr. Halloran attended Central High School in St. Paul and graduated from St. Thomas College in 1910. He graduated from the University of Minnesota Medical School in 1915 and served his internship at St. Joseph's Hospital in St. Paul during the years 1915-1916. After completion of his internship he was surgical assistant to Dr. W. C. Carroll until the time of his entry into the army during the first World War. While in the army he served at Base Hospital #71 in France.



Walter H. Halloran, M.D.

Upon his return from service he located in Jackson, Minnesota, and was associated with Dr. W. C. Portmann of that city. Together with his father he built and maintained the Halloran Hospital in Jackson for approximately thirty-five years, until it was sold.

In 1920 he married Tereas Ryan, R.N., of St. Paul. Doctor and Mrs. Halloran presently have seven living children. Father Walter Halloran, S.J., a teacher at Marquette University; Mrs. William Harrington, the wife of Dr. William Harrington, Professor of Medicine at Miami Medical School; Dr. William R. Halloran of Milwaukee, Wisconsin; John I. Halloran, a lawyer in Jackson, Minnesota; Mark J. Halloran, M.D., a postgraduate student at Barnes Hospital, St. Louis; Sister M. Gilberte, O.P., a teacher in Chicago, and Mrs. Loren Vorlicky, the wife of Dr. Loren Vorlicky of Oakland, California.

For several years Dr. Halloran has been a member of the Board of Directors of Minnesota Blue Shield and is presently serving as its Secretary.

At the present time, Dr. and Mrs. Halloran maintain the Julie Billiart home for severely mentally and physically handicapped infants in Jackson.

Dr. Hansen was born in Minneapolis on May 22, 1890, and he attended grade and high schools in Minneapolis, after which he entered the University of Minnesota and received his Bachelor of Science degree, followed by his M.D. degree in 1915.

During the First World War, Dr. Hansen served as a Medical Officer with the first division of the United States Army, and at the close of the war he entered the Army of Occupation as it moved into Germany. He received the Croix de Guerre from the French Army and the Silver Star for the United States Army.

Dr. Hansen has been a member of the usual medical societies and was President of the Hennepin County Medical Society, the Minneapolis Academy of Medicine, the Minnesota Academy of Ophthalmology and Otolaryngology, as well as of the American Academy of Ophthalmology and Otolaryngology. He was chairman of the Section on Ophthalmology of the American Medical Association, a delegate from Minnesota to the American Medical Association House of Delegates, and also on the Board of Governors of the American College of Surgeons.

He was a member of the University faculty for thirty-nine years, retiring as Professor and Head of the Department of Ophthalmology in 1958.

Erling Wilhelm Hansen, M.D.

Dr. Hansen was born March 18, 1890, in Hecla, Brown County, South Dakota of Danish homesteader parents. After high school, she went to the Northern Normal and Industrial School in Aberdeen, South Dakota, and later entered the University of Minnesota. In 1913 she graduated with a bachelor of science degree and in 1915 received her doctor of medicine degree. Dr. Hansen served her internship in the University of Minnesota Hospital.

In 1916 she became associated with Doctors S. Marx White and John Sajoie in the practice of medicine in Minneapolis. Dr. Hansen was also an instructor in medicine from 1917-1927 at the University of Minnesota. She joined the Nicollet Clinic in 1921 and is still practicing internal medicine there.

She was married in 1934 to the late Dr. Jennings C. Litzenberg.

Olga S. Hansen, M.D.

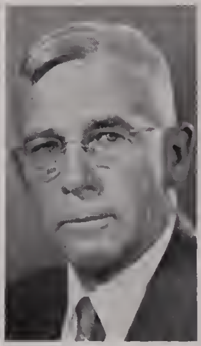
Dr. Havens, a plastic surgeon of the Mayo Clinic from 1928 to 1955, was born on January 22, 1890, at Hallville, Illinois.

In 1912 he received the degree of bachelor of science from Drake University, and in 1915 that of doctor of medicine from the Rush Medical College of the University of Chicago. He served as an intern in Saint Luke's Hospital in Chicago in 1915, and entered the private practice of medicine in Winona, Michigan, in 1916. In 1919 he removed to Waupun, Wisconsin.

Dr. Havens came to Rochester, Minnesota, on April 1, 1926, as a fellow in otolaryngology of the Mayo Foundation. On October 1 of that year he was appointed a first assistant in laryngology, and on April 1, 1928, he was appointed a member of the staff of the Mayo Clinic as a consultant in the Section of Otolaryngology, Oral and Plastic Surgery. From 1929 to 1934 he was an instructor in laryngology in the Mayo Foundation, Graduate School, University of Minnesota; and in 1934 he was advanced to assistant professor. From 1941 to the time of his retirement on April 1, 1955, he was an associate professor.

In 1956 Dr. and Mrs. Havens removed to Riverside, California.

Dr. Havens became widely known in the field of plastic surgery as a result of certain procedures which he either introduced or modified to enhance their usefulness.



Fred Z. Havens, M.D.

Dr. Havens was certified as a specialist in otolaryngology and plastic surgery. He was a member of the American Academy of Ophthalmology and Otolaryngology, the American Association of Oral and Plastic Surgery, the American Laryngological, Rhinological and Otological Society, the American Medical Association, the American Laryngological Association, the American Society of Plastic and Reconstructive Surgery, the Minnesota Academy of Ophthalmology and Otolaryngology, the Minnesota State Medical Association, and the Alumni Association of the Mayo Foundation.

Continued

Reuben A. Johnson, M.D.

Dr. Johnson was born July 30, 1889 in Colton, California. He attended public school at the South High School, Minneapolis and graduated from the University of Minnesota Medical School in 1915. He did postgraduate study in Vienna, London and Berlin and completed his internship at Abbott Hospital in Minneapolis.

He served as a first lieutenant in World War I, and after the war began his practice of medicine in Minneapolis.

Dr. Johnson was associated at one time with Dr. William E. Petersen and served on the Abbott, Mount Sinai and St. Barnabas hospital staffs. He was a clinical professor of medicine at the University of Minnesota and a diplomate of the American Board of Internal Medicine.

In the past, Dr. Johnson has served as first vice president and chairman of the Board of Censors of the Hennepin County Medical Society and was a former first president of the Minneapolis Society of Internal Medicine. He also was a past secretary and treasurer and past president of the Minnesota Society of Internal Medicine.

He was married to Gladys Sievers, now deceased, and they had three children. Dr. Johnson presently is spending his retirement in Minneapolis.

Herman O. McPheeters, M.D.

Dr. McPheeters, F.A.C.S., F.I.C.S., F.A.C.A., was born January 31, 1891, in Mankato, Minnesota. His family then moved to Aitkin, Minnesota, where he was graduated from the Aitkin High School in June 1909. Thereafter he received his premedical education in Hamline University and then transferred to Northwestern Medical School where he acquired his M.D. degree in June, 1915.

He served his internship at Wesley Memorial Hospital, after which he entered the Army and served for a year in the First World War.

In 1919 he became associated with N. H. Schelderup, M.D., who was a general surgeon, and remained with him until 1924, when he independently entered into general practice and surgery. After 1935, he limited his work to vascular surgery and continued as one of the outstanding authorities on the treatment of varicose veins. In this capacity he did a considerable amount of research work and developed some of the principles that are still used in the treatment of varicose veins, stasis, ulcers and vascular problems of the extremities. Many of his original ideas still remain the basis upon which numerous vascular problems are solved.

He was licensed in both the states of Illinois and Minnesota in 1917.

He married Ethel T. Anderson of Redwood Falls, Minnesota; they have one son, George Edward, and a daughter, Mary Ann (Mrs. Looe Baker, Jr.).

Dr. McPheeters is now retired from active practice; but he does some consultation work and remains constantly active in his numerous hobbies.

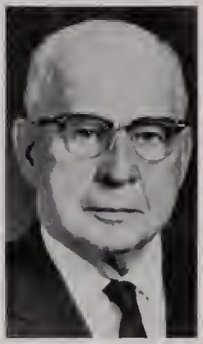
Frank B. Mach, M.D.

Dr. Mach was born in New Prague, Minnesota in 1891. He entered the University of Minnesota Medical School in 1909 and graduated in 1915. After completing an internship at Minneapolis General Hospital, he started practice in Northeast Minneapolis, where he has remained ever since. At the present time, he has his son, Dr. John R., practicing with him.

During the first World War, Dr. Mach entered the United States Army Medical Corps as a Captain and was attached to the Royal Army Medical Corps in the European Theater, where he obtained valuable experience and contributed a much needed service to his country. He then returned to Minneapolis and has been affiliated with the staff at St. Mary's Hospital since 1916.

He was married to Alice Neary in 1924. They have two sons, Robert F. and Dr. John R., and one daughter, Mrs. Mary Clifford Peterson.

Dr. Mach enjoys an active general practice and in his spare time he amuses himself with gardening and other hobbies. He has not missed a Minnesota home football game in fifty-six years.



Fredolph H. Magney, M.D.

Dr. Magney was born on March 4, 1886, in Trenton Township, Pierce County, Wisconsin. He attended public school in Bayport, Minnesota and graduated from Amery High School in Wisconsin.

He then became interested in pharmacy and attended the Minnesota Institute of Pharmacy, becoming a registered pharmacist in 1908, after which he practiced pharmacy in Duluth and Minneapolis for a few years.

This activity in pharmacy apparently stimulated Dr. Magney's interest in medicine and he then entered Gustavus Adolphus College for some additional academic work and transferred to the University of Minnesota, finally receiving his medical degree in 1915. He served his internship at the City and County Hospital in St. Paul. After his internship, he entered the Army Medical Corps as a regimental surgeon with the 125th Field Artillery, serving with the American Expeditionary Force in France as a Captain.

After his return to the United States, he entered practice in Duluth in 1916, and continued to remain in active practice in the field of surgery until 1962.

He has a long list of achievements, having been President of the St. Louis County Tuberculosis and Health Association and Chief of Staff at St. Luke's, St. Mary's and Miller Hospitals. He has also been Chief of the Surgical Section at St. Luke's and Miller Hospital and has been Chief of the Obstetric Section of these hospitals.

Dr. Magney has fulfilled the responsibility of numerous civic duties and has proven his sterling qualities by serving as President of the Duluth Chapter of the Professional Men's Club of America, the St. Louis County Tuberculosis and Health Association and the Duluth Surgical Society. He has been a Director of the Duluth Chamber of Commerce and the Duluth Chapter of the American Red Cross.

For thirty years he served on the Minnesota State Board of Medical Examiners. He is a member of the Rotary Club, the Pilgrim Congregational Church, the T. W. Hugo A. M. & A. F. Lodge, the Scottish Rite, the Duluth York Rite and the Aad Temple. He was President of the Hay Fever Club of America. He was justifiably awarded the Distinguished Service Medal by the Minnesota State Medical Association and he was also awarded the Silver Beaver by the Boy Scouts of America. He was married to Ruth Taylor in 1922, and they have four sons, Roy Taylor, Robert Gorham, Paul Herman and Mark Jonas.

Though Dr. Magney still maintains interest in medical organizations and serves as a consultant on numerous occasions, he is enjoying a well deserved semi-retirement.

Morton P. Morse, M.D.

Dr. Morse was born and went to school in LeRoy, Minnesota, which is a little town near Rochester.

He entered the University of Illinois in Chicago and graduated with an M.D. degree in 1915. This same year he was licensed to practice medicine in Iowa. He served his internship in what is now the Hennepin County General Hospital.

During World War One, he served as Captain in the Medical Corps of the United States Army.

Since 1917, Dr. Morse has been in practice in LeRoy, Minnesota.

Continued

Edgar R. Sather, M.D.

Dr. Sather was born at Willmar, Minnesota, in April, 1889.

He attended the University of Minnesota for his premedical training and then the University of Iowa at Iowa City, where he received his medical degree in 1915. He interned at the Minneapolis General Hospital.

He practiced at Spring Valley, Minnesota, from 1916 to 1922, with two years out for Service in the British Army. In December 1922, he moved to Alexandria, Minnesota, and has practiced there ever since. In August 1919, he was married to Ragna Molstad of Spring Valley, Minnesota. They had two children, Mrs. James Swenson of Alexandria, and Rev. Edgar Sather, who is at present teaching in Anatolia College in Thesseloniki, Greece.

Dr. Sather has been president of the Park Region Medical Society, a delegate to the Minnesota State Medical Society, and first vice president of the State Society. He has also been President of the Park Region Section of the Ameican Academy of General Practice. In 1931 he was president of the Alexandria Kiwanis Club and the next year was Commander of the American Legion Club 87 of Alexandria. In 1955 he was moderator of the Central division of the Congregational Church and the next year was named moderator of his home church.

He has been Chief of Staff of both Douglas County and Our Lady of Mercy Hospitals in Alexandria. He is a member of the Indigent Doctors Committee and has been a member of that committee since its inception.

Dr. Sather is still in active practice.

Charles W. Waas, M.D.

Dr. Waas was born in Pittsburgh, Pennsylvania, on December 1, 1888. The major portion of his medical education was acquired in Canada, where he attended St. John's College in Winnipeg and graduated from the University of Manitoba cum laude in 1915. He obtained his license to practice from the Medical Council of Canada in June, 1915, after which he served his internship in the Winnipeg General Hospital.

He entered the practice of general medicine in North Dakota, where he remained for five years, when he transferred to St. Paul, where he has conducted his practice up to the present date. He is a member of the Ramsey County Medical Society, the Minnesota State Medical Society, the American Medical Association and the American Association of General Practitioners.

Clayton K. Williams, M.D.

Dr. Williams was born in Minneapolis on February 2, 1891. He received his Bachelor of Science degree from the University of Minnesota in 1914 and his M.D. degree the following year. He served his internship at St. Joseph's Hospital and began practice in St. Paul in 1916, where he has remained.

His practice was limited to internal medicine. During the Frst World War he served as Captain in the United States Army Medical Corps.

He was married to Natalie C. Carter in 1919.

He was Secretary of the Ramsey County Medical Society from 1944 to 1946 and President of that Sociey in 1948. In addition to belonging to the usual county, state and national medical societies, he is a member of the Minnesota Academy of Medicine.

Curbstone Consultation

Muscular Problem Among Alcoholics

QUESTION: In a recent discussion among a group of colleagues one of them stated he had the impression some type of muscular syndrome was occasionally associated with chronic alcholism. I am aware of the neuropathies that may accompany alcoholism but have never heard of an associated muscular problem among alcoholics. Do you have knowledge of such a condition?

ANSWER: There has recently been described both an acute and a chronic muscular syndrome associated with marked alcoholic abuse. In the acute syndrome patients present with muscular aching, tenderness, and edema. Some have associated renal damage with hyperpotassemia. Extensive necrosis of muscle fibers can often be demonstrated on pathological examination. The chronic variety apparently manifests itself in one of two ways. In one group there may develop gradually a symmetrical weakness of the proximal limb and girdle muscles without evidences of an acute process. In the other group there are no symptoms of muscle disease, but electromyography and biopsy can demonstrate changes.

Muscular strength apparently returns following cessation of drinking and institution of proper medical care.

Transhepatic Cholangiography

QUESTION: Would you do transhepatic cholangiography if you did not plan to do a laporatomy?

ANSWER: I would not do percutaneous transhepatic cholangiography unless I planned to do a laparotomy. However, if I found a normal biliary ductal system, removing the possibility of obstructive jaundice, I would not proceed with operation, since it would be contra-indicated. We have had patients with long-standing complete obstructive jaundice, particularly those with carcinoma of the pancreas with metastases, who have not tolerated the procedure well and in whom we have inserted a small polyethylene tube and proceeded to allow the ductal system to be decompressed by this method.

Frank Glenn, M.D.

Fracture–Trauma Conference

Fat Embolism and Pelvic Fracture

Management of the patient who has sustained a fractured pelvis entails preparedness on the part of the physician to treat the associated injuries (i.e. extremity, head, thoracic, abdominal) which occur so frequently in the type of accident which produces pelvic fractures. He must also be alert to the presence of continuing retroperitoneal hemorrhage from the fracture site which may in itself cause death by exsanguination. Another complication is fat embolism. This may occur with any fracture and, in fact, has been described in instances where no fracture was detected.[1]

In the following case history in spite of a rather minimal displacement of the pubic rami at the fracture site and no clinical evidence of other significant injury the patient's hospital course was complicated by fat embolism which very nearly proved to be fatal.

Case History

An 81-year-old male pedestrian was struck by a slow moving automobile on the afternoon of 12/7/62. He was admitted to Swedish Hospital where x-rays (iFgure 1) revealed fractures of the left superior and inferior pubic rami with minimal displacement of the fracture fragments. An old degenerative arthritis of the left femoral head was also detected. He was well oriented and in good general condition for his age. He was put to bed and closely observed.

The following morning the patient was doing well, bright and alert, until at 1:30 P.M. or approximately 18 hours following injury, he became incontinent of urine and noted some slight difficulty in breathing. That evening he seemed obtunded and failing to eat, he was given an intravenous solution of 5% dextrose and water. During the night his condition deteriorated and by 8:00 A.M. 12/9/62 he was in acute respiratory distress and comatose. An emergency tracheostomy was performed, which afforded him considerable relief. At this time petechiae were found to be present over his chest and upper arms. A diagnosis of fat embolism was made and confirmed by the finding of free fat on urine examination.

He was slightly improved on 12/10/62 and nasogastric tube feedings were initiated. On 12/12/62 he was able to take food orally and the tube feedings were discontinued During the patient's hospital stay his hemoglobin fell from 12.9 gms % to 9.7 gms. %. However, on discharge it had risen to 12 gms %. Gradual improvement continued until at the time of his discharge to a nursing home on 1/2/63 it was apparent that he had entirely recovered his mental faculties and he had no difficulty with respiration following removal of his tracheostomy tube.

Continued

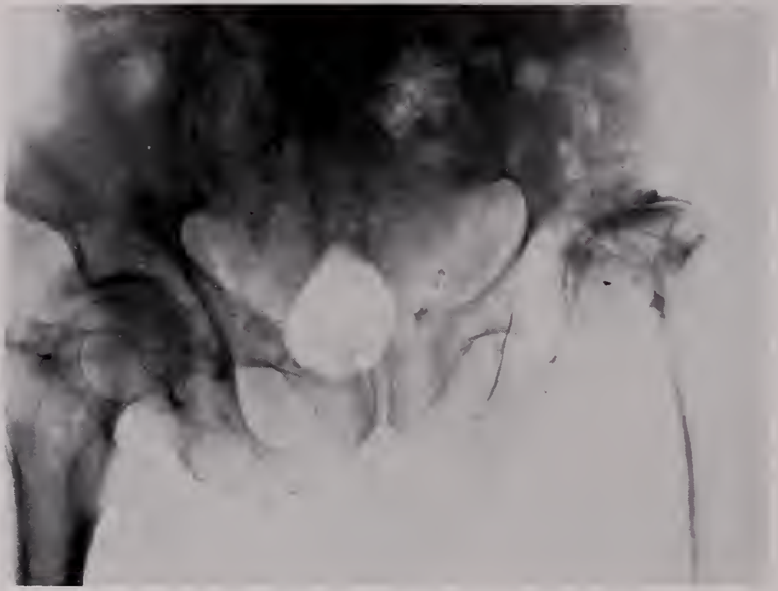

Fig. 1 — X-ray demonstrating fracture of left superior and inferior pubic rami.

Discussion

How often does fat embolism occur in cases of trauma? Is it produced by the entry of bone marrow fat or local fat into the general circulation or is it a result of a rather precipitous change in the lipid content of the blood?

These questions continue to provoke different answers from different authors with different supporting bits of evidence.[2-5] Nevertheless, there is no question but that, as in the case presented, fat embolism may occur after what would otherwise appear to be a rather minimal injury as well as with more severe trauma. For this reason any patient with an injury severe enough to require hospitalization should be closely observed.

Signs

A change in the patient's mental awareness, the development of dyspnea, the appearance of petechiae over the chest, upper arms and conjuctivae, and fever are objective signs that may be observed in patients with fat embolism. An unexplained sudden drop in the serum hemoglobin level may be related. The pulmonary symptoms are usually the first to be manifested.

Tests

Sputum and urine samples may be stained with Sudan III and if present the doubly refractile fat can readily be seen under the microscope. It is possible to biopsy the petechiae to prove the diagnosis. In stained sections of pathological specimens the fat appears as in Figure 2.

Treatment

Intravenous solutions of fat solvents have been recommended but in general, the results from their use have been disappointing. In the recent past, steroids have been tried and the results have been encouraging. Further data on their use is needed before recommendation for general

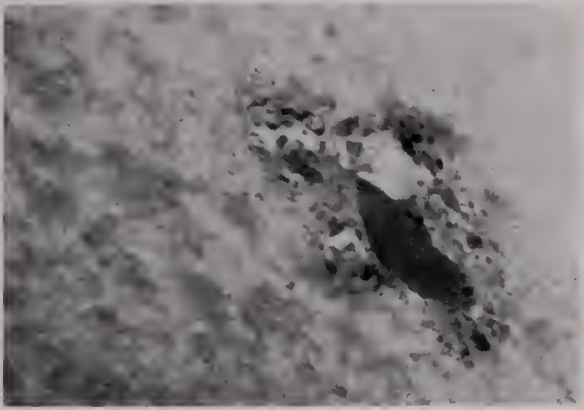

Fig. 2. — Photo micrograph of fat emboli in brain tissue.

use can be made. The use of intravenous heparin with its well known lipolytic effect has been recommended; however, to use such an agent in the early hours following a fracture, especially one in which massive bleeding may go undetected, would seem to be unduly dangerous.

The physician and hospital staff can provide good supportive care which includes intravenous or nasogastric fluids, an adequate airway with proper respiratory tract toilet, careful management of an indwelling urinary catheter, and good nursing care. Many of these patients will clear their vascular system and tissues of the offending emboli if they can be successfully tided over the first few critical hours by judicious medical management.

Medicine Comes of Age

By mid-nineteenth century Medicine, in one respect, no longer trailed behind the Church and the Law. On January 25, 1856, The (London) Times wrote: ‘Of the three learned professions, the medical has attained the highest character for disinterestedness. Hard things are said of the cupidity of the clergy, the wealth of certain benefices affording a strange contrast to the poverty of the primative Church; still harder things are said of the lawyers, who are supposed to eat the contested oyster while the plaintiff gets one shell and the defendant the other; but there is probably no class of the community generally so free from mercenary motives as the members of the medical and surgical profession.’*

Tumor Conference

Synovial Sarcoma, Lower Extremity

A 16-year-old otherwise healthy male presented a history of noticing a lump in the upper outer area of the left thigh at the region of the great trochanter. He has no recollection of bruise or injury. Over a four-month period the mass gradually increased in size and was painless. A somewhat ill-defined soft mass presented 5 x 4 cm. No skin or vascular changes were evident on inspection.

Under general anesthesia, a well-encapsulated 8 x 6 cm. mass that easily shelled out was removed by enucleation. There appeared to be an attachment to, or near the capsule of the hip joint. It did not arise from the hip joint itself.

Microscopic examination revealed a typical mixture of sarcomatous-appearing cellular background with scattered areas that appeared glandular in configuration. Diagnosis, therefore: Malignant synovioma synovial sarcoma. The case is presented for recommendation for future therapy.

Discussion and Review

Ackerman[1] describes synovial sarcoma as an intimate intermingling web of adenomatous structures and a sarcomatous-like stroma. Stout[6] suggests that the tumor may arise from embryonic synovioblasts near, but not from, the joint. The origin near the joints is an important differential since synovial hyperplasia, hemangiomata, etc., arise within joint structures.[1]

An early review of 104 cases reported by Haagensen and Stout[4] in 1944 cite only three cases free of tumor in five years. However, a later series reported from New York Memorial Cancer by Pack and Ariel[5] in 1950, present much better figures (absolute 5-year survival of 19.1 per cent, therapeutic 5-year of 23.5 per cent and a 10-year of 16.7 per cent). The difference in the two series appears to be based upon more radical treatment in the Memorial Hospital group. Haagensen and Stout recommended more radical treatment because of the poor results from less aggressive treatment and Pack and Ariel attributed the improvement to employment of more radical methods. This frequently involved amputation.

Pack and Ariel[5] advised that the tumor be approached first by application of a tourniquet above the lesion, then aspiration or very small incisional biopsy, and finally if the biopsy was reported as malignant synovioma, an amputation was done below a second tourniquet — that is, between two tourniquets. The double tourniquet technique is designed to prevent pickup implantation from the biopsy to the amputation site.

Continued

Reports[5,1,3] indicate a better chance for cure in the younger age group. Crocker and Stout[3] suggest a well planned wide local excision in children under 15. Whenever the location is feasible, an amputation may, therefore, be avoided. Regional lymph node dissection is advocated[5,4,6] since this particular sarcoma has an appreciable (16.6 per cent[5]) node involvement.

Recommendations

Since the lesion in this patient is in an unfortunate location, too near the hip joint to permit an adequate wide local excision, and since even a hip disarticulation would fall short of adequate criteria for cure, a hemipelvectomy is the only operation designed to fulfill the requirements of adequate excisional therapy. Such a procedure presupposes a negative chest X ray and absence of evidence of metastases. Furthermore, a sarcoma, particularly of this high grade malignancy, does not, in fact, have any capsule. The apparent encapsulation is tissue compressed by tumor growth and in all likelihood, tumor cells will be found in adjacent tissue. Amputation after recurrence appears has been quite unsuccessful; none in the Haagensen[4] series have achieved 5-year survival.

If surgical treatment is refused, then X-ray therapy should be employed with at least some chance of prolongation of life.[5]

Neurological Conference

Retinitis Pigmentosa*

Dr. Robert Soll

Retinitis pigmentosa is a rare condition, whose importance is shared by many other conditions which are similarly rare, that is how readily might it be recognized in a patient? If it is recognized, what treatment, if any, can be employed to improve the condition and what counsel can be given to the patient and his family? These are very crucial questions in this type of case and bear significantly on the patient's future life.

Dr. Alan R. Sinaiko**

The patient is a 16-year-old boy who complains of difficulty in hearing and seeing. Apparently his hearing difficulty has been present since age five. He has been followed at the University Hospital since 1955 and during the past nine years has had four audiograms, which revealed a decreased acuity for higher frequencies. He was given a hearing aid after his initial hospital visit, but unfortunately, because of numerous small problems, he did not wear it consistently.

His visual problems began approximately two years ago when he first noticed a decreased visual acuity at night. One year ago he went to an ophthalmologist and was given glasses for myopia. Within six months he had required stronger glasses because of continued decreasing vision; however, since that time he believes his vision has remained unchanged. For the past year he has virtually complete night blindness.

Family History

His family history is significant in that he has one 12-year-old sister who is deaf, and also a paternal grandmother, great uncle and great aunt who are deaf. There is no definite history of any previous visual difficulty in the family. The patient has had an eighth-grade education marked with numerous difficulties in school, primarily because of inability to hear

*Sponsored by the U. S. Public Health Service Grant N2502A63. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals. The pediatric conferences are held the first and third Wednesdays of every month from 3:15 to 4:15 p.m. The adult conferences held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Robert W. ten Bensel, in Pediatrics, and Dr. Robert Soll, in Adult Neurology.

Held November 5, 1964.

**Student doctor, University of Minnesota Medical Center.

Continued

and slowness in reading. During the past four months he has been working as a laborer for a construction company.

Examination

His most recent physical examination revealed a definite hearing loss, and on funduscopic examination numerous darkened pigmented patches distributed in a typical "bone spicule" configuration were apparent at the periphery of the retina. The macular area itself was normal. His visual acuity at this time was 20/60 in the right eye and 20/50 in the left eye without glasses; with corrective glasses his central acuity was approximately 20/20 in both eyes; but his peripheral vision was decreased to approximately one half of normal. The remainder of the physical examination including neurological examination was normal.

Dr. John Brantner*

The present psychological tests indicate a border-line performance. These tests were given to him in writing and approximately duplicated the school situation. Since he was handicapped at school by difficulty in reading, these tests may also be inconclusive.

Nonverbal Intelligence Tests

On a nonverbal intelligence test such as the Porteus Mazes he attained an average IQ of 104. His basic abilities would be considered in the average range. You would expect him to handle with ease practical situations such as those in contruction work or even higher-level work, where he would doubtless react normally and not appear defective. The appearance of his disability or handicap would be noted only if he were asked to read or if he tried to use abstract thinking or verbal skills. He does not show in either the Porteus or the Graham Kendall tests, both of which are quite sensitive, any signs of organic brain damage.

He was also given the Minnesota Multiphasic Personality Inventory, but the results were of a random sort. He either did not understand the items, or more likely was unable to read them. The scores on the various scales show that he answered 53% of one of them, 47%, 48%, 49% and so on, approximately a 50% average, and resulting only in the type of profile that can be obtained by shuffling the cards and guessing half of them true and half false: a totally invalid personality test.

So this is a boy who is functioning at a border-line level in verbal skills without showing brain-damage evidence on the tests. He probably has average or slightly above average intellectual skills, but he is handicapped. These results point to further testing that ought to be done, such as a full diagnostic intellectual work-up to identify areas of this handicap in verbal skills, especially since we do have tests that are suited for non-hearing or hard-of-hearing subjects. If he intends to advance further in schooling, I think that he could profit by reading diagnostic tests which would determine exactly which skills of the many that are involved in reading are below normal. Also, we have personality tests that do not require reading; and I think that he ought to be given these. For example, the Rorschach test does not require the ability to read or to write.*

Dr. Robert Letson*

Retinitis pigmentosa is primarily a selective degeneration of the neuroepithelium of the retina. As it is usually manifested in the equatorial region of the eyes, the pupils should be dilated on examination. Early stages of retinitis may appear before age 10 or during the first decade, although it may appear later. The progression is slow, but usually complete blindness is present by age 50; however, I have seen some patients in their 60s who still have good central vision. There are accumulations of pigment which are spicular in type, often surrounding the retinal vessels; these gradually migrate or progress to involve the entire posterior pole of the eye as well as the peripheral retina. In addition to these black accumulations of spicules or fine bone spicule formation, there is often narrowing of the vasculature of the retina to the point that the vessels almost disappear.

In later stages when the optic nerve has degenerated, optic atrophy is also apparent. There is degeneration of all the layers of the retina, but primarily the rod and cone layer is involved. Macrophages pick up pigment and migrate toward the vessels. Many of them disintegrate, leaving pigment accumulations around the retinal vessels. Often when visual fields are done on these patients, a ring or doughnut-shaped scotoma will be found. This is because the degeneration is rather selective, starting between 15°-30° from the point of central vision, and proceeding both centrally and peripherally, widening the scotoma and eventually involving the macular area.

Clinical Syndrome

The clinical picture is really a syndrome, because many of these individuals often have high myopia, cataracts, and deafness associated with the retinal changes. Occasionally we have to remove the cataracts which have developed, but unfortunately, such removal may not necessarily help the patient's vision, since retinal changes have also occurred. Whether the lens or the retina is the relatively greater factor in causing decreased acuity is difficult to establish. Therefore treatment must be individualized in each case. Frequently we can improve central visual acuity. In a youngster, myopia usually will continue to increase until age 25 or 30.

The Type of Cataract

Usually a cataract does not appear until the fourth or fifth decade as a later manifestation of the disease: an ordinary senile-type cataract, although the patient is really presenile. Both central and peripheral types of cataracts occur; there is not just one specific type such as diabetics develop.

Prognosis

The prognosis is usually unfavorable, because symptoms will definitely progress to eventual blindness. Unfortunately we have no specific treatment as far as the retinal disease is concerned, but as has been mentioned, keeping the refraction up to date and removing the cataract are of value; in this way, patients can be helped for a while. Usually by age 50 their

---

Continued

visual function is gone; but some have maintained vision until age 60 or 70.

Differential Diagnosis

The differential diagnosis includes chorioretinitis due to inflammation. This disease, however, causes a focal and sharply demarcated lesion and may be unilateral. The phenothiazine drugs when given in large doses for long periods may cause a similar picture in the fundus, but this entity can be excluded by the history. There are other primary retinal degenerations which may resemble retinitis pigmentosa, but a discussion of these is not of general interest.

Dr. Soll

The counsel that the physician gives to his patient and the patient's family concerning the eventual disability of the patient is very important. Of course, with this young boy, it is very important for him to know that he may be able to function well for many, many years and lead a productive life in spite of the fact that he has trouble with his vision and hearing. It would also be well if we could detect all such children before age 10 so as to at least inform the parents of this possibility before they have other children.

Mrs. Gloria Gross*

The patient has had the same type of hearing loss since he was first seen in 1955. Both pure tone and speech audiometry remain unchanged from previous results. Two ears respond similarly to pure tone. There is no suggestion of middle ear pathology that would require attention. We do find that acuity for the low frequencies is virtually normal but that he has a fairly sharp loss for high frequencies. This means that he can hear the human voice and the vowels almost as well as we can. Without the use of amplification, some of the consonants are only partially audible; therefore, without amplification, this boy can hear speech, but only incompletely and with difficulty.

The Body-worn Hearing Aid

He came into the clinic not wearing his aid, and such a fact is usually significant. The instrument he presently owns is a body-worn type, to be placed underneath his clothing. Both clothing noise and low frequencies are amplified by the instrument.

The Ear-level Hearing Aid

With the ear-level instruments produced today, extraneous noise is greatly reduced. This patient has responded well to the ear-level type of instrument; he is much better able to understand lip-reading. I don't believe that the patient is at all interested in the cosmetic appearance of the hearing aid; I don't think he wants an ear-level instrument just because it looks nicer.

Speech Adversely Affected

The patient's speech has been adversely affected by his hearing loss in that it corresponds to what he hears. Consequently, some consonants are distorted. I would assume that much of the boy's poor progress in school could be attributed to the fact that he was not hearing well. If he were in a classroom without a hearing aid and were not able to lip-read, then he would not know what was being said. A hearing aid is definitely recommended and I am confident that he could learn to use one.

---

*Clinical audiologist, University of Minnesota Medical Center.

Dr. Soll: At what frequencies do the consonants occur specifically?

Dr. Frank Lassman:* Consonants such as l, n, b, and r, are subserved by energy approximately in the range of 700 to 800 cycles up to about 3000 cycles. Other consonants such as t, p, k, sh, f, and soft th would be subserved by energy above 1200 cycles to about 3000 cycles. There is energy at other frequencies beyond 3000 cycles in these consonants, but the presence or absence of this energy is not critical to the auditory discrimination of these consonant sounds. The most important range, then, would be from approximately 1000 cycles to 3000 cycles; this is an octave and a half in length, the range in which his hearing is down about 40 to 50 decibels.

Dr. Richard Magraw:** Would there be any difference in the audibility of a man's or woman's voice?

Mrs. Gross: No, not necessarily; the point that I tried to make earlier was that he does hear a voice, and if it is a fairly good voice, then he should be able to discriminate speech fairly well. But he will make errors in differentiating some consonant sounds from others.

Dr. Lassman: If the woman is a soft-spoken individual, it might have some effect on his ability to hear, especially in a noisy background. But Mrs. Gross's point about the precision of articulation is the most critical one.

Mr. Thomas Fawcett†

The only problem this family has ever presented to the county welfare department has been for authorization to help procure his hearing aid. Both parents have visited us several times. The first time I was aware of the patient's visual problems was probably one month ago. The family lives on an 80-acre farm. They are trying to make a living there but it is difficult. Both parents are also working at other pobs. The community probably has not been too sympathetic as far as the patient is concerned. This fact is possibly part of the patient's troubles in school. His father has said that when his son was in the eighth grade, he was doing about straight F work. He would have been better off in the third grade. The whole difficulty according to the father was that the patient couldn't read. Consequently he dropped school and got a construction job, and from all reports, he has done very well. His employer has been very satisfied, although I don't know how long this may last. If his problem is progressive, he may have to get trained for some other type of work. The likelihood that he will do quite well for many years is very good.

†County Welfare department, Gaylord County.

Continued

Mr. Romeyn Clarke:* The boy seems to be a rather likable young fellow. The family is financially marginal and have had a very hard time. The mother, age 34, gives the impression of being a very energetic person who is working hard to make ends meet. The father, age 44, first started farming right after marriage on his own family's farm; but this didn't work out. After five years he had to go out and work in a cheese factory, and now he is working in a manufacturing plant. His take-home pay is not over $70 a week for a family of six. The patient is the second of four children. An older brother, age 17, is now finishing high school; a sister, age 12, also has a hearing problem; another brother, age 10, seems to be doing well. The home is not too well kept up. The mother has to do outside work whenever she can, although she doesn't like to leave the family. She works during the canning season, but when there is a poor crop like this year, she attempts to get another job. She raises a little stock and some grain and does all the work on their little place. They do a large amount of subsistence farming since that is the only way they can get by. Now I presume that she is a fairly permissive mother, not driving the children very hard.

There was a hearing aid problem in that the patient was teased at school. He frequently had to fight and often came home in a bloody state. For this additional reason it has been difficult to make him and his sister wear their hearing aids. The mother finds it very hard to say to the children, "You just have to do this," because she remembers her own experience of being teased when she was young. At this point she feels that she can adjust to the hearing difficulty; but she has also been told that the patient is going to be blind and she doesn't have the heart to talk about it.

Finally, I would like to add that the patient's recent job experience has apparently been very good for him. Wearing a hearing aid which has any kind of cord, as his mother explained to me, interferes with his work; perhaps this inconvenience could be eliminated by an ear-level hearing aid. He is working on a construction job as a helper, carrying bricks up to other workers or helping load concrete. Often he has to be told several times to do things. In general this has been a good experience except that fellow workers who started with him now are getting a raise and he isn't. This is hard for him to take.

Dr. Milton Alter**

The association of retinitis pigmentosa and deafness is known as Usher's syndrome, an entity well described in ophthalmologic literature. Retinitis pigmentosa is actually found in a wide variety of clinical disorders. A survey of Pennsylvania school children who had visual acuity under 20/200 revealed 1.3% with retinitis pigmentosa. Another survey in Switzerland revealed one individual in 7000, or 0.0143%, affected with retinitis pigmentosa.

There are several varieties of hereditary transmission of retinitis pigmentosa that have been reported in different pedigrees. According to Francois, the autosomal recessive variety accounts for about one third of the cases. There is an autosomal dominant variety which accounts for about 20% of the cases; 4% follow a simple recessive form of inheritance. There is also a rare form which is sex-linked. The remainder of the cases were either sporadic or the data was inconclusive to establish the nature of the transmission.

---

*Senior social worker, University of Minnesota Medical Center.

**Instructor, department of neurology, University of Minnesota Medical Center.

Autosomal Recessive Trait

If both parents are carriers of an autosomal recessive trait, it is transmitted to ¾ of the offspring on the average, but only ¼ receive a double dose and show the trait. Males and females are affected with equal frequency. See Figure 1.

	R	r
R	RR	Rr
r	Rr	rr

Retinitis pigmentosa is represented as the small r, and normal by the large R.

Fig. 1

The diagram also illustrates that one half of the offspring are asymptomatic carriers and one fourth are normal. If a carrier now mates with another carrier, again one fourth of the offspring would be affected. However, since the trait is rare, a carrier is more likely to marry a normal individual, in which case no offspring would be affected, but one half would be carriers. See Figure 2.

	R	r
R	RR	Rr
R	RR	Rr

Fig. 2

It is readily appreciated that a carrier is more likely to marry another carrier if he mates with a close relative. Hence, the consanguinity rate is high among parents of individuals with rare recessive traits. The more rare the trait, the higher the rate. An average of 26.7% consanguinity has been reported for retinitis pigmentosa, compared to less than 1% in the general population.

Sex-linked Recessive Inheritance

Sex-linked recessive inheritance is more complicated. One half of the male offspring of a carrier female are affected, and one half of the daughters are carriers and can transmit the disorder to their sons. The female contributes one of her two X chromosomes to the zygote. Since only one of her X chromosomes is defective the risk that the disease will be transmitted is 50%. If the defective female X chromosome unites with

Continued

a normal X chromosome contributed by the father, a carrier daughter results. The normal X supplies the genetic information lacking in the defective X chromosome. On the other hand, if the father contributes a Y chromosome which unites with a defective X chromosome, an affected son results. He shows the trait because he has no normal X chromosome to supply the genetic information lacking on the defective X chromosome received from the carrier mother. See Figure 3.

	X	X^r
X	XX	X^rX
Y	XY	X^rY

X = normal chromosome
Xr = defective chromosome
Y = male chromosome

Fig. 3

It has recently been shown that only one of the X chromosomes in the female is active in a given cell. The X chromosome which is inactivated is selected at random very early in embryogenesis. On the average, one half of the female's cells are normal and the other half defective. Some slight defect in the carrier female, therefore, would be anticipated and, in the case of retinitis pigmentosa, this has actually been found. Female carriers of retinitis pigmentosa may show some pigmentary degeneration of the retina as well as defective color vision, mainly for blue and green. A scintillating golden reflex from the macula and perimacular area has also been described.

Autosomal-dominant Inheritance

The autosomal dominant form of inheritance is straight-forward. One half of the offspring of an affected individual are also affected in this situation. See Figure 4.

	R	R	
R	RR	RR	Normal
r^D	Rr^D	Rr^D	Affected

r^D = dominant type of retinitis

Fig. 4

Sporadic cases may be new mutations, phenocopies of the genetic disorder, or inheritance from individuals who had the defect but in whom the defect did not penetrate. Penetrance is a useful concept which has perhaps been abused by some geneticists. If an individual shows any stigmata of the trait, the disorder has penetrated; the degree to which it has penetrated is called expression. While penetrance is an all-or-none phenomenon, expression is quantitative.

The Patient's Pedigree

In our patient's pedigree, we are probably dealing with an absence of penetrance. The maternal grandfather had 16 siblings who were entirely normal. The paternal grandmother, however, was deaf and had a deaf brother and sister. One of the patient's siblings was still-born and a 12-year-old sister has some evidence of deafness as well as early signs of retinitis. This appears to be transmission of a dominant trait, and some of the other siblings not yet examined probably also show evidence of the disease. See Figure 5.

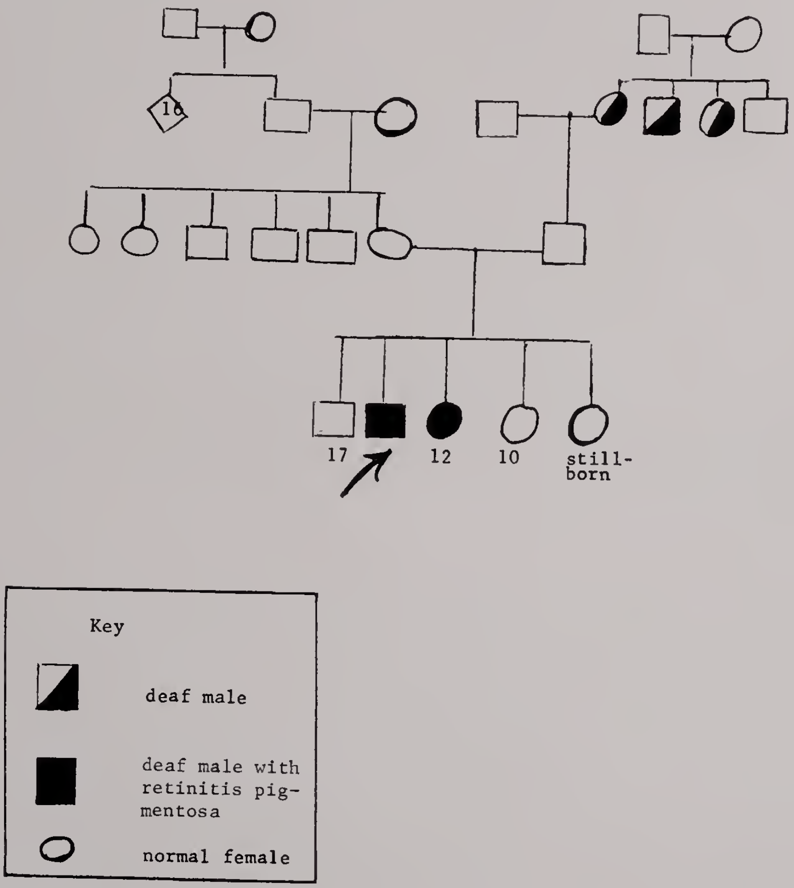

Fig. 5

Agents which can produce retinitis pigmentosa give rise to nonheritable phenocopies. The defect in such cases cannot be transmitted. It has been reported that phenothiazine, thioridazine and ethylphenothiazine can cause retinitis pigmentosa.

Some eye signs associated with the defect include narrow vessels, optic atrophy, decreased color vision and an abnormal electroretinogram. Less often, glaucoma and microphthalmia occur. Retinitis pigmentosa has been

Continued

observed in Laurence-Moon-Biedl syndrome, in Friedrich's ataxia, and occasionally in Marfan's syndrome.

Experimental work of interest includes the observation that about 50% of affected individuals have positive F II latex fixation tests. In some individuals the 19S macroglobulins are increased, suggesting that the disorder is not localized to the retina.

A strain of rats with retinitis pigmentosa has been studied. A decreased ability to carry out anaerobic glycolysis in the retinal cells has been found in them. The defective enzyme was believed to be triose phosphate dehydrogenase. In addition, amino acid abnormalities were discovered. Taurine was increased in affected retinas; glutamic acid was only half the normal value, and aspartic acid was synthetized at 2-4 times the normal rate. The implications of these studies for humans are intriguing, but a relationship has yet to be demonstrated.

It appears that the trait is a dominant one in our patient, and thus we would predict that 50% of the patient's children would be affected. It is unlikely that he would marry an affected individual.

If the father shows neither deafness nor retinitis pigmentosa, he represents a lack of penetrance. However, he must have the defect in order to have transmitted it to the patient and the patient's sister.

Dr. Sinaiko: How do you know that the deafness in this paternal grandmother, aunts and uncles was also due to this gene?

Dr. Alter: That is an educated guess. We don't know for certain because we are lacking information about the father, but we know he has a deaf mother, aunt and uncle. We know the patient is both deaf and has the eye defect. It is convenient to assume that all those affected have the same disease, until proven otherwise.

Dr. Lassman

For many good reasons, some of them historical, this boy has not had the advantages of special educational tutoring and rehabilitative services which are available from both public and private resources in Minnesota today. The physicians present should take note that a hard-of-hearing youngster with related speech problems who has had difficulty learning to read and has had some other associated problems in school has a wealth of resources waiting to assist him. It needs only the physician to properly trigger the mechanism. The Minnesota Legislatures of 1957 and 1958 made it financially possible for a school district to pay the salaries of remedial-reading teachers, speech correctionists, teachers of the hearing-impaired and the slow-learning, etc. They also made it possible for a school district to purchase necessary remedial services and tutoring from adjacent school districts. Later legislation improved opportunities for the transportation of youngsters needing special helps to the source of the help. The law makes the proper education of special children mandatory and not just permissive; i.e., the school district is responsible to "educate" its children or must locate such educational opportunity elsewhere.

Another important development is the establishment of responsibility for special education in a section of the Minnesota Department of Education, called the Division of Special Education. Mr. Ellsworth Stenswick heads this division which includes a hard-working staff who can help interpret the Special Education laws to school boards, superintendents, and principals. In theory, no youngster with a visual and hearing problem having trouble in school need go without assistance. In practice, this sometimes takes some aggressive action by the physician to assist local educational agencies to both recognize their problem (the handicapped child) and to find a solution (state special supports for special tutoring, speech correction, etc.)

There are other special resources developing locally and regionally: the Audiology and Speech Pathology sections of the University Hospital; the College of Education Psycho-Educational Clinic; the Speech Clinics at UMD, Mankato, St. Cloud and Moorhead State Colleges; the speech programs at St. Paul Rehab Center and at the Kenny Institute; the Minneapolis and St. Paul Hearing Societies; and many more. One of the most important and helpful agencies is the Division of Vocational Rehabilitation, Minnesota Department of Education, which will support education, vocational training, and job placement. The State Department of Public Health and Division of Crippled Children's Services, Department of Public Welfare, hold regional speech and hearing clinics. A most interesting recent development is a Speech and Hearing Camp run by the Minnesota Society for Crippled Children, which looks like a useful summer project for the next few years.

Handicapped children need special help as early as possible. The resources are here — now — in Minnesota. It is up to us to help get the two together.

Robert Soll, M.D.
Moderator
University of Minnesota
Medical Center

Participating in the conference: Alan R. Sinaiko, student doctor; Dr. John Brantner, clinical psychologist (University of Minnesota Medical Center); Miss Helen Kretchmer, supervisor and assistant professor of social service (University of Minnesota Medical Center); Dr. Robert Letson, resident physician, department of ophthalmology (University of Minnesota Medical Center); Mrs. Gloria Gross, clinical audiologist (University of Minnesota Medical Center); Dr. Frank Lassman, professor of speech and audiology (University of Minnesota Medical Center); Dr. Richard Magraw, associate professor of medical psychology and director of the comprehensive clinic program (University of Minnesota Medical Center); Mr. Romeyn Clarke, senior social worker(University of Minnesota Medical Center); Mr. Thomas Fawcett, county welfare department, Gaylord County; Dr. Milton Alter, instructor, department of neurology (University of Minnesota Medical Center); and Dr. Robert Soll, chairman, adult community services (University of Minnesota Medical Center).

Subsequent to the conference this patient was given the Rorschach, the Chicago Non-verbal Examination, and the Gates Reading Diagnostic Tests. These showed that his intelligence is in the low average range with considerable deficiency in verbal skills. His judgment, foresight, grasp of abstract concepts and memory are normal. The personality tests do not show any unusual patterns of thought, beyond a mild lack of positive pleasure. Conclusion: low average to average intellectual capacity, normal personality, reading deficit but with ability to benefit from remedial training.

Our greatest glory is not in never falling but in rising every time we fall.
— *Confucius*

**Depend on low-cost,
low-dosage Prolixin
— once-a-day**

Prolixin is a dependable tranquilizer that provides your patient with low cost therapy. No other tranquilizer costs less. Safe and convenient for office use—Prolixin in a single daily dose provides prolonged and sustained action. Markedly low in toxicity and virtually free from usual sedative effects —Prolixin is indicated for patients who must be alert. Clinical experience indicates fluphenazine hydrochloride is especially effective in controlling the symptoms of anxiety and tension complicating somatic disorders such as premenstrual tension, menopause, or hypertension—also useful for anxiety and tension due to environmental or emotional stress. When you prescribe Prolixin you offer your patient effective tranquilization that is low in cost, low in dosage and low in sedative activity.

THE
SQUIBB
TRANQUILIZER

WHEN TRANQUILIZATION WITHOUT SEDATION IS DESIRABLE, TRY

PROLIXIN®

SQUIBB FLUPHENAZINE HYDROCHLORIDE

SIDE EFFECTS, PRECAUTIONS, CONTRAINDICATIONS: As used for anxiety and tension, side effects are unlikely. Reversible extrapyramidal reactions may develop occasionally. In higher doses for psychotic disorders, patients may experience excessive drowsiness, visual blurring, dizziness, insomnia (rare), allergic skin reactions, nausea, anorexia, salivation, edema, perspiration, dry mouth, polyuria, hypotension. Jaundice has been exceedingly rare. Photo-sensitivity has not been reported. Blood dyscrasias occur with phenothiazines; routine blood counts are recommended. If symptoms of upper respiratory infection occur, discontinue the drug and institute appropriate treatment. Do not use epinephrine for hypotension which may appear in patients on large doses undergoing surgery. Effects of atropine may be potentiated. Do not use with high doses of hypnotics or in patients with subcortical brain damage. Use cautiously in convulsive disorders.

AVAILABLE: 1 mg. tablets. Bottles of 50 and 500.

For full information, see your Squibb Product Reference or Product Brief.

SQUIBB Squibb Quality—the Priceless Ingredient

Grand Rounds

Hyperparathyroidism

The incidence of hyperparathyroidism is difficult to estimate but it certainly is not great. However, an understanding of this complex disease is important because it leads to irreversible renal damage, and if recognized early in its course can be cured by surgery. Although the pathologic physiology and anatomic changes in primary hyperparathyroidism are quite well understood, the etiology is not known.

In an analysis of 100 cases at the Massachusetts General Hospital, ages ranged from 12 to 72 years with 80% between three and 60. The female to male ratio was 7:3.

Pathology

From Table 1 it is apparent that the most frequent cause of hyperparathyroidism is parathyroid adenoma, the location of which is as variable as that of the normal glands. The upper parathyroid glands develop from the fourth branchial pouch, usually descend to the level of the cricoid cartilage, and are situated on the posterolateral surface of the lobes of the thyroid gland. Occasionally there is an invagination of the parathyroid gland into the capsule of the thyroid, and in rare cases the parathyroid gland may be located within the body of the thyroid.

The lower parathyroid glands originating from the third branchial pouch are much more erratic in their location, varying from their normal position at the lower border of the thyroid gland to a location in the anterior mediastinum and occasionally behind the esophagus. Approximately 75% of adenomas occur in the lower glands. The number of glands is also variable, ranging from four to 10. With a functioning adenoma, there is usually atrophy of the other glands. However, in 3% of cases multiple parathyroid adenomas may be present.

The mean size of a single human parathyroid gland is approximately 5 x 5 x 3 mm., and the total weight of all four glands is 118 mg. The glands are reddish or yellowish-brown in color with distinct stalks. There are

---

Presented as a Medical Grand Rounds at Mt. Sinai Hospital, Minneapolis, July 28, 1964.

Continued

three cell types present: chief cells, which are 6-8 μ in diameter and contain glycogen; the "wasserhelle" or water-clear cell, which is larger and vacuolated; and the oxyphil cell, which contains no glycogen and varies in size from 11 to 14 μ. There is controversy as to whether this cell is associated with any function.

In an adenoma there can be any mixture of these various components. Most of the adenomas are comprised mainly of chief cells; the nuclei of which are usually large, filling about half the cells. In adenomas, cells with two or three nuclei are not uncommon, so that darkly-staining pyknotic nuclei may lead to an incorrect diagnosis of malignancy. Mitosis and anaplasia are not seen in adenomas and are still valid criteria of carcinoma. The cells are usually arranged in broad bands or in the shape of acini in a highly vascular network.

Carcinoma

These tumors are usually functioning. At operation the surgeon may recognize their presence by their adherence to the surrounding tissue. Metastases usually appear first in the regional lymph nodes. Microscopic examination shows no rim of normal parathyroid tissue as may be found in adenomas, capsular invasion, and extension of the capsular connective tissue into the tumor as dense contiguous septa with glandular cells that are larger and more atypical. It is not known whether adenomas may be the origin of carcinomas.

Hyperplasia

The gross appearance is different from that of an adenoma in that the gland is irregular in shape with projections. The glands are soft and a darkish brown. On microscopic examination the capsule is thin and no normal parathyroid tissue can be seen. The only type of cell present is the wasserhelle cell, with variable patterns of arrangement. All the glands are enlarged, rather than atrophic as found in the presence of an adenoma or carcinoma.

Bone Lesions

Extreme decalcification results in poorly formed, very pliable bones,

TABLE I

Types of Parathyroid Gland Pathology in Primary Hyperparathyroidism***

Pathologic Classification		Cases	
		Number	Per cent
Single parathyroid adenoma		343	89.1
Multiple parathyroid adenomas	10 cases		
With polyendocrine adenomas*	10 cases		
Without polyendocrine adenomas	11 cases		
Total cases		21	5.5
Primary parathyroid hypertrophy and hyperplasia**		19	4.9
Parathyroid carcinoma		2	0.5
Total cases		385	100.0

*Multiple parathyroid adenomas associated with tumors of the pancreatic islet cells or of the anterior pituitary gland or of both glands.

**Primary (wasserhelle-cell) parathyroid hyperplasia.

Williams Endocrinology
3rd Edition, Saunders publ.

resulting in marked deformities, a condition called osteitis fibrosa or von Recklinghausen's disease of bone. The decalcification may be either generalized or localized; in the latter, cysts may be produced. Within the medullary cavity brownish areas may be seen which represent the proliferation of large numbers of osteoclasts. The cysts and decalcification result in weak bones and fractures in severe cases.

Kidney

The specific lesion is the deposition of calcium in the renal tubules and the interstitial tissue, i.e., nephrocalcinosis, resulting in impaired renal function with an increased incidence of pyelonephritis. Renal calculi are very common (Table 2).

TABLE 2
Clinical Features of Urolithiasis in 50 Patients with Functioning Parathyroid Tumors

	No. Patients
Recurrent calculi	25
Bilateral calculi	29
Opaque calculi	50
Single calculus	7
Multiple calculi	33*
Nephrocalcinosis	10

*Staghorn calculi in five patients.

R. J. Veenema
California Medicine
Vol. 95, No. 2

Metastatic Calcification

Deposition of calcium in soft tissues may occur. The kidneys are the most common site, but metastatic calcification may be seen in the lung, stomach, pituitary gland, and in almost any other location.

Calcium and Phosphorus Metabolism

The basic function of the parathyroid glands is the regulation of calcium and phosphate metabolism. The various clinical pictures of hyperparathyroidism are the end result of hyperfunction.

Both calcium and phosphate, although principally found in the skeleton, are, in varying amounts, distributed throughout all the body compartments, and their presence is essential in maintaining several important processes. Among the many roles of calcium are:

1. Participation in formation of bones and teeth (the skeleton containing over 99% of the body calcium).
2. Maintenance of normal blood coagulation by serving as a cofactor in the conversion of prothrombin to thrombin.
3. Regulation of membrane permeability.
4. Maintenance of normal cardiac rhythmicity.
5. Regulation of excitability of nerves and muscles.
6. Maintenance of normal muscular contraction.
7. Maintenance of normal renal tubular concentrating mechanisms, i.e., calcium excess will cause lesions of the distal renal tubules, resulting in a loss of concentrating power.

Continued

8. Maintenance of normal enzyme activity.

9. Normal development of the fetus during pregnancy and of the newborn infant during lactation.

The main site of calcium absorption is the upper small intestine, especially the duodenum. Once calcium has reached the colon it is present as insoluble salts and is not available for absorption. The absorption of calcium is enhanced by several factors; chief among these are D vitamins, parathormone acting in the presence of permissive amounts of vitamin D, and the state of the calcium stores of the body.

In plasma, it is the ionized calcium which is metabolically important, not the total amount. Alkalosis or an increase in phosphate or citrate may result in more bound calcium, while the total amount remains normal. The reverse is true in hypoproteinemia, where the total calcium value may be decreased, but the ionized calcium fraction may be normal.

Ten per cent of the total excretion of calcium is through the kidney, the remaining 90% through the intestinal tract. The major route of phosphate excretion is the kidney rather than the intestine.

For clinical purposes we may express the relationship of the calcium and phosphate ions in the plasma by the relationship, calcium conc. x phosphate conc. equals a constant. A rise in the concentration of either ion will result in a fall of the other.

Actions of Parathormone

On the Kidney

Parathormone causes an increase of renal tubular reabsorption of calcium, and there have been three suggested actions in regard to phosphate and the kidney: parathormone may increase the glomerular filtration of phosphate; increase the tubular reabsorption of phosphate; and increase the tubular secretion of phosphate.

Action on Bone

The direct effect of parathormone appears to be the conversion of cells from osteoblastic to osteolytic activity. This has two consequences: decreased bone formation and increased bone reabsorption, resulting in the simultaneous breakdown of both the matrix and mineral components of bone, and a release of calcium and phosphate ions.

Action on the Gastrointestinal Tract

Parathormone causes an increase in the absorption of calcium from the small intestine. This action seems to occur by the hormone, acting in the presence of permissive amounts of vitamin D improving the concentration gradient across the mucosa.

DeLuca[2] in a study of kidney mitochondria found that vitamin D and parathyroid hormone act synergistically to promote the release of calcium from isolated mitochondria and that the presence of the vitamin is necessary for this action to take place. This in vitro demonstration has been supplemented by the in vivo studies of Rasmussen[3] who demonstrated that administration of 200 to 500 units of bovine parathormone induces severe hyperparathyroidism in the vitamin D-fed rat but has little or no effect upon calcium and phosphate concentration in the vitamin D-deficient animal.

Calcitonin

Recently, evidence has been presented that there probably exists in addition to parathormone, a second active substance, Calcitonin, which acts to lower serum calcium. Copp,[4,5] using an isolated thyroid and thyroid-parathyroid perfusion system, demonstrated that perfusion with high calcium concentration resulted in a fall in serum calcium within a few hours only if the parathyroid glands were part of the perfusion system. This effect was different from that of parathyroidectomy, which resulted in a much longer period of time before the drop in the serum calcium occurred. It has also been shown that this perfusion effect is obliterated by parathyroidectomy[6].

Tests of Parathyroid Function

At present a sensitive and reliable method for measurement of parathormone is not available. Such a test would directly measure parathyroid function. Isotopic-immunologic techniques show promise and may be the answer to this problem.

Serum Calcium

Levels of serum calcium measured by the EDTA chelating technique[7] greater than 10.5 mgm% are definitely abnormal, and suggest the presence of hyperparathyroidism. Calcium measurements by this method are reliable screening tests for parathyroid hyperfunction.

Serum Phosphate

This is characteristically very low in primary hyperparathyroidism in the absence of renal damage. The measurement of serum phosphate is, however, less reliable and more variable than serum calcium.

Serum Alkaline Phosphatase

In cases with significant bone involvement, alkaline phosphatase is elevated. Chiandussi[8] has reported chromatography of the various fractions of serum alkaline phosphatase, but as yet these have no diagnostic advantage. Alkaline phosphatase is an index of bone formation, not parathyroid function.

Ionized Fraction of Calcium

Rose[9] discovered that by adding a small amount of murexide dye to a solution of calcium ion at or near the neutral pH, the subsequent colour intensity was proportional to the calcium ion concentration. This test is of value in borderline cases, especially those associated with abnormal serum proteins, azotemia, or other complicating biochemical features.

Urinary Calcium Excretion

a. Qualitative Sulkowitch Test. Buffered oxalate solution added to urine produces a calcium oxalate precipitate and a cloudy solution. However, the correlation with quantitative calcium measurements is poor and this is an unreliable index of hypercalciuria.

b. Quantitative measurement. The patient is placed on a diet in which the total ingested quantity of calcium per 24-hour period is known. This

Continued

usually is approximately 150 mgm. After three days preparation, the urinary 24-hour calcium excretion is measured. Normally, an amount equal to ingested calcium is excreted in the urine. In primary hyperparathyroidism the urine excretion of calcium exceeds the intake by more than 50 mgm. An excessive excretion of calcium indicates an inability to maintain calcium balance.

Cortisone Test

Two hundred to four hundred mgm. daily of cortisone are given for seven days and the serum calcium determined daily. A fall to normal serum calcium levels indicates secondary hypercalcemia and is against the diagnosis of primary hyperparathyroidism. This test is generally quite reliable, but there are occasional falsely positive or negative results.

Tubular Reabsorption of Phosphate

One of the primary actions of parathormone is to increase the excretion of phosphate by the kidney tubules. The filtered load of phosphate presented to the tubules can be calculated by multiplying the serum phosphate concentration by the creatinine clearance. By calculating the total phosphate excreted, i.e., the urinary phosphate concentration times the volume of urine, the tubular reabsorption ratio of filtered phosphate can then be calculated.

Gordon had found that 43% of his series of surgically proven hyperparathyroidism had TRP values greater than 80%.[10] Low values for tubular reabsorption of phosphate, characteristic of primary hyperparathyroidism, can occur in other hypercalcemic states such as multiple myeloma and sarcoidosis.

Serum Chloride Levels

Wills[11] compared serum chloride levels in primary hyperparathyroidism and those obtained in other disorders associated with hypercalcemia, such as sarcoidosis, hypervitaminosis D, and myelomatosis and found that in hyperparathyroidism there is almost always an elevation of serum chloride above 102 mEq./L., whereas in secondary hypercalcemia the serum chloride is almost always below this level.

Calcium Turnover in Bone

A number of tests have been designed to evaluate the rate of calcium turnover in bone.

a. Intravenous strontium test — devised by Fraser.[12] As the metabolism of strontium is similar to calcium, the rate of skeletal deposition of calcium can be followed with a radioactive tracer dose of strontium. Strontium gluconate is injected intravenously and the concentration of strontium in the urine and plasma is measured for the next six days. From the curves of radioactivity in plasma and urine, the rate of transfer of calcium into bone can be calculated. Two indices are thus obtained: CaE — the exchangeable calcium pool, and CaB — the rate of calcium deposition in bone. The advantages of this test over the one to be described next are that it is more sensitive; a smaller dose of radioactive material is needed; and the radioisotope has a shorter half-life than Ca^{45}.

b. Intravenous radiocalcium infusion test using Ca^{45}. This test is similar to the strontium test except that plasma and urine concentrations must be followed for two weeks. Rich[13] has described a test using a constant intravenous infusion of Ca^{45}, shortening the observation period.

Rapid Calcium Infusion Test

Goldsmith has described a new modified rapid calcium infusion test.[14] Both normal and hyperparathyroid subjects exhibit a progressively increasing phosphaturia between the hours of 8 A.M. and 12 A.M.. By calculating the ratios of phosphate concentration to creatinine concentration in the urine a curve can be constructed. The 9 A.M. value is considered 100% and subsequent ratios expressed in relation to it. A baseline is obtained on the first day; on the second day 180 mg. of calcium is injected intravenously. The curve in normals shows depression after calcium infusion when compared to the baseline curve. The principle underlying the test is that normally elevation of serum calcium results in a depression of parathormone secretion, increased phosphate retention, and decreased urinary excretion of phosphate, which acts to lower the urine phosphate-creatinine ratio. In hyperparathyroidism, there is a lack of response to increased calcium levels and the depression of the curve does not occur. In Boeck's sarcoid a characteristic sawtooth curve is produced by calcium infusion.

Serum Citrate Level

It has been reported that serum citrate levels are elevated in primary hyperparathyroidism.[15] Hodgkinson has demonstrated that while serum citrate is usually elevated, this is closely correlated with serum calcium and is not an indication of bone involvement.[15]

Bone X Rays

Bone surveys by X ray may be used to determine if typical bone changes are present. X rays of the hands, skull, and lamina dura may be particularly helpful.

Kinemometry

With the hypotonicity sometimes present, one may use kinemometry to document the increased contraction and relaxation time of tendon reflexes.

Clinical Manifestations of Primary Hyperparathyroidism

It is almost an understatement to categorize this as a disease with protean manifestations. The classical presentation of "stone, bone, abdominal groan and mental moan" is far too rare to be relied on. The signs and symptoms can be put into three groups, depending on their origin.

Skeletal Syndrome

Pain in bones and joints, spontaneous fractures, cysts in the bones of the skull, deformity of the long bones, kyphosis, scoliosis or other deformity of the thorax, waddling gait.

Urologic Syndrome

Nephrocalcinosis, renal calculi. There are varying figures reported for the frequency of primary hyperparathyroidism as the cause of renal calculi; the usually accepted one is from 5-10%.

Continued

Hypercalcemic Syndrome

With earlier diagnosis an increasing number in this category are being discovered, perhaps comprising 15% of cases. Symptoms include malaise, muscular weakness, bradycardia, psychiatric manifestations, polyuria, polydipsia and constipation. Polyuria and polydipsia are not infrequent complaints and may be due to the hypercalcemia itself rather than to renal insufficiency.

St. Goar[16] in a series of 45 proven cases had 16 in which gastrointestinal symptoms were a predominant feature and eventually lead to the diagnosis. Hypercalcemia causes a neuromuscular excitability, eventually leading to a decreased tone of the gastrointestinal tract. The large bowel atony leads to constipation while gastric atony results in dyspepsia, nausea and vomiting.

Frequently Associated Diseases

There are certain diseases which, because of their frequent association with hyperparathyroidism, warrant consideration of this diagnosis when encountered.

Peptic Ulcer

Hypercalcemia is capable of producing gastrointestinal symptoms, but in addition peptic ulcer can be demonstrated in 10-15% of patients with primary hyperparathyroidism. The increased incidence of peptic ulcer may be due to a direct action of parathormone on the gastric mucosa.[17] Children or young women with peptic ulcer should especially be investigated for hyperparathyroidism. The conventional treatment of peptic ulcer by milk in a patient with hypercalcemia may precipitate acute calcium intoxication.

Pancreatitis

Keating[18] recognized the significance of this association and also pointed out the difficulty in diagnosis.

Multiple Endocrine Adenomatosis

Hyperparathyroidism may be associated with hyperinsulinism and/or pituitary adenomas. It has also been reported in association with the Zollinger-Ellison Syndrome.

Problems of Acute Parathyroid Intoxication

Since Lowenburg[19] produced a hypercalcemic crisis in man by the accidental administration of an overdose of parathormone, it has been evident that hypercalcemic crisis can occur. Since that time, many cases have been well documented.[20] Wilson[21] recently reported a series and listed the clinical manifestations as follows:

CNS	GI	RENAL	CVS
Headache	Anorexia, nausea	Precipitation of calcium in renal tubules.	Supraventricular tachycardia
Restlessness	Vomiting		Shortened QT intervals (EKG)
Disorientation	GI hemorrhage		Circulatory arrest
Coma	Acute pancreatitis	Progressive oliguria	

There have been 27 cases documented, of which eight were operated upon and survived. In all but two, the serum calcium was greater than 17 mgm.%

However made, the diagnosis of primary hyperparathyroidism must be made with assurance, so that the surgeon may have complete confidence in making his dissection as radical as necessary to locate and remove the offending glands. The treatment of this disease is primarily surgical.

Case Report

A 25-year-old married white woman was admitted to Mount Sinai Hospital 6-8-64 for investigation of an elevated serum calcium first discovered a month earlier while she was hospitalized for an illness diagnosed as acute pyelitis. An intravenous pyelogram revealed minute sparse flecks of calcium in both kidneys. The serum calcium was elevated on two determinations. The patient had had two other episodes presumed to be kidney infections, both of which responded to treatment. There was no history of kidney stones, of excessive milk or antacid ingestion, or of vitamin D consumption. She denied weakness, emotional lability, cramps, epigastric pain, indigestion or hematuria. She thought she drank more fluids than normal, but denied having polyuria or nocturia. She had a chronic problem with constipation and if she did not take a laxative she would have a stool only once a week.

Physical examination revealed a well developed, well nourished white female who was very co-operative. The physical neurological examination was entirely normal except for mild tenderness at the left costovertebral angle.

Laboratory studies gave the following results: Hemoglobin 12.5 gm%, WBC 5,000 with a normal differential, hematocrit 39%, sedimentation rate 4 mm./hour, urinalysis negative. A number of serum calcium determinations (EDTA chelation method) gave levels of 10.6, 11.0, 10.8, 11.7, 11.8, 11.2, 11.4 mg%. Normal upper limit 10.5 mg%. Serum phosphorus measurements varied from 2.2 to 2.8 mg%. Serum sodium and potassium were normal. BUN was normal. The serum chloride was 109 mEq./L. Cholesterol was 125 mg%. Alkaline phosphatase was 10 KA units.

The patient was placed on a 150 mg. calcium intake for three days, following which 24-hour urinary calcium excretion was 222 mg., 239 mg. and 189 mg. The tubular reabsorption of phosphorus was 70% (normal 80-90%). Kinemometry was within normal limits. A rapid calcium infusion test was performed but gave confusing results which could not be interpreted.

Chest X ray was normal. A dental film showed the lamina dura to be present. Skull films, and upper GI series, and an electrocardiogram were all normal.

On 6-17-64, an operation was performed, and in the region of the right lower parathyroid gland an adenoma was discovered. The other parathyroid glands did not appear atrophic. The adenoma was an ovoid, moderately firm nodule weighing 1.35 grams, which on microscopic examination showed a mixed cell pattern composed of chief cells, transitional water-clear cells and a few aggregates of oxyphils. There was a thin, intact capsule and at one pole a small fragment of normal parathyroid tissue.

The patient's postoperative course was uneventful. Postoperatively the serum calcium varied from 8.5 to 9.3 mg%. The serum phosphorus level rose to 3.4 mg%, and the serum chloride was 107 mEq./L. The patient was discharged on 6-23-64 in excellent condition.

Butazolidin®
brand of
phenylbutazone

in rheumatoid arthritis

Geigy

Therapeutic effects
A number of workers have reported major improvement in 50-75% of cases, with some successful cases going into complete remission.

In responsive cases, improvement is generally seen within a week, so that trial therapy need seldom be continued beyond this period. Alleviation of pain is followed quickly by improvement of function and resolution of effusion or other signs of active inflammation. Relief of arthritic symptoms is quite frequently accompanied by increased appetite, gain in weight and an improved sense of well-being.

The initial response is usually maintained without dosage increases; indeed, initial dosage is often reduced for maintenance purposes.

Salicylate or steroid therapy can usually be diminished or, in some instances, eliminated.

Psoriatic arthritis responds in the same way as rheumatoid arthritis but the skin lesions are usually not affected either favorably or adversely by treatment.

Precautions
Before prescribing, the physician should obtain a complete history and perform a complete physical and laboratory examination, including a blood count.

The patient should be kept under close supervision and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools.

If coumarin-type anticoagulants are given simultaneously, the physician should watch for excessive increase in prothrombin time.

Side effects
The most common side effects are nausea, edema and drug rash. Infrequently, agranulocytosis, generalized allergic reaction, stomatitis, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug.

Contraindications
These include: edema, hypertension, or danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when other potent chemotherapeutic agents are given concurrently because of the increased possibility of toxic reactions; when the patient cannot be seen regularly; when the patient is senile.

Note: The physician should be fully aware of dosage, precautions, side effects and contraindications as contained in the complete prescribing information.

Abstracts, Briefs and Commentaries

THE DURABILITY OF AORTO-ILIAC ENDARTERECTOMY, A ROENTGENOLOGIC AND PATHOLOGICAL STUDY OF LATE RECURRENCE

The authors present their results in the use of endarterectomy as a primary method of reconstruction in an occlusive process which is largely confined to the aorta and common iliac arteries, and they describe their technique and results in 104 cases of those operated. Certain classes of patients were excluded in order to investigate the persistence of good results and the incidence of recurrent disease in a minimum period of two years of observation. Sixty-seven total cases were submitted to the study; of these 67 patients studied there were 151 sites of operation.

In the follow-up angiographic studies there was an appearance of angiographic changes of either occlusion in 4%, or stenoses without occlusion in 41% of the 100 operated sites on the iliac artery. Of the 51 operated sites of the aorta, there was no evidence of occlusion, but there was evidence of partial stenosis in 15%. However, of all the abnormal changes noted, 84% were classified as class I, those in which narrowing was less than 30%. In the few recovered specimens it is interesting to note that the recurrent lesions showed true secondary atherosclerosis by gross and microscopic examination. The authors also point out that the endarterized segment does not re-endothelialize but, as confirmed by other studies, develops a pseudo-intima of organized fibrin deposits closely mimicking the pseudo-intima of the plastic arterial prostheses. The authors also felt that there was no significant difference between the use of endarterectomy in this type of patient and the use of arterial prostheses in the over-all long-term evaluation.

It was their conclusion that these observations in no way detract from the great clinical value of aorto-iliac endarterectomy but that they point up the obvious fact that the surgical treatment of arteriosclerosis is not lastingly curative. The authors also point out that in the nine cases followed angiographically for two years or more *after* the onset of recurrence, all showed progression in the arterial disease; of these nine patients, four had complete occlusion.

Continued

This is a very interesting paper because it indicates that significant atherosclerosis developed in the diseased arteries despite endarterectomy. However, they did not state whether arterial prostheses also developed atherosclerotic changes in the pseudo-intima, but did intimate that the end results were approximately the same. Other studies by DeBakey suggest, however, that the pseudo-intima of a prosthesis is less likely to develop atherosclerotic changes than the percentage recorded by these authors would indicate. Certainly this type of evaluation in long-term results needs continued careful survey. Furthermore, the authors did not reveal the exact status of the other adjunct medical treatments of atherosclerosis, i.e., the rigid control of diabetes mellitus, a low cholesterol diet, and abstinence from smoking and drugs. This type of observation would be extremely helpful in correlating concomitant medical control of and surgical procedure in atherosclerosis.

GALLBLADDER DISEASE IN DIABETICS

Diabetics do not withstand the complications of gallbladder disease as well as other people.

Between 1947 and 1960 a total of 145 diabetics with cholelithiasis and cholecystitis were admitted to Massachusetts General Hospital. Mundth compares results in these cases with those in 150 nondiabetics operated on for acute cholecystitis.

Of the 145 diabetics 43 were treated without operation. Of the 102 patients treated surgically, 99 had a cholecystectomy with or without exploration of the common duct and three a cholecystostomy.

The operative mortality was 22 percent and the incidence of postoperative complications was 51 percent in the surgically treated diabetics, as compared with 0.7 percent and 11 percent respectively in the nondiabetics. Diabetics have a special liability to gallstones; incidence is 25 percent in diabetics against eight percent in nondiabetics.

Patients with mild diabetes tolerated elective biliary tract surgery very well. The operative mortality and morbidity were not significantly different from those in nondiabetics.

It is recommended that early elective cholecystectomy should be carried out in all diabetics known to have cholelithiasis, unless a specific contraindication is present.

MAMMOGRAPHY

The Cancer Bulletin of December, 1962, came to my attention several months ago. It contained an extensive review of the research done by a group at the University of Texas M. D. Anderson Hospital and Tumor Institute on Mammography.

X-ray study of the female breast dates back fifty years, but it was not until recently considered of great practical value. This was attributed to poor X-ray equipment and tubes, poor and inexperienced technicians, and the inexperience of the radiologist. The Texas group, consisting of several specialists representing different fields of medicine, reported results of 2,000 mammograms on 1,204 patients in 1962. X-ray examination and diagnoses were made without knowledge of the patient's history or clinical findings. Working together with the Eastman Company, a much superior film was developed. The group also worked with research men from the manufacturers of X-ray equipment, with the result that technicians improved and radiologists matured in the interpretation of films.

The group invited radiologists to visit their organization to become familiar with their methods and avoid making the same errors they had made. Dr. Robert Egan, the radiologist playing a large part in the program at Texas University, is now at the Methodist Hospital of Indiana at Indianapolis, Indiana. Taking part in the mammogram study were 24 participating institutions, one of which was the University of Minnesota Medical School. All of their radiologists were given a five-day indoctrination in mammography. Two hundred radiologists have taken this course of training. Dr. Egan states that it takes two years to properly train a cytology technician and six months with accumulating experience for a pathologist.

I wrote to Dr. Egan personally for more information about their work and later publications, and received from him a fine personal reply, together with eight reprints concluding his work through 1964. He stated that interest had increased with the publications on the technique of good mammographs. Procedures had not been publicized to a great extent until fundamentals were established and it was recognized that good films were a necessity. The accuracy of interpretation of films improves with experience.

Dr. Egan had personally performed 3,818 consecutive roentgenographic examinations. He states that benign lesions interpreted as malignant were the greatest source of error. Eighty-five clinically unsuspected carcinomas were diagnosed. Co-operation with clinicians, surgeons, and radiologists is important, and nonpalpable lesions should be localized for the surgeon at the time of biopsy. Bilateral simultaneous carcinomas were detected by mammography in 3 per cent and bilateral successive cancers in 4 per cent of examinations. Cancer of the remaining breasts was found in 28 of 278 patients who had had one breast removed previously.

Collected data indicate that roentgenographic and pathologic diagnoses agreed in 85 per cent and that the correct diagnosis was 80 per cent for cancer by mammography and 90 per cent for benign lesions. X-ray study of the breast has now been extended to include the axilla.

Periodic radiographic examinations have been recommended. By comparison of films taken at six to 12-month intervals, slight changes occur that would not be detected without a series of films. By this means breast cancers have been diagnosed before there was any clinical evidence of their presence.

The very excellent article on mammography by Gersholn-Cohen in the December issue of Minnesota Medicine coincides with the results of studies here reviewed. His work is recognized several times by Egan. If anything, Dr. Egan and his colleagues report higher percentages of accuracy by clinical diagnosis (70 per cent), by radiologist (90 per cent), and by combined clinician and radiologist (95 per cent).

Discussion

Dr. Egan graciously sent me eight reprints on technique and interpretation of films, with much data reported in the way of statistics. I am turning these all over to the Hennepin County Medical Society library.

They seem to feel that the surgeons have been responsible for part of the nonacceptance of mammography. My feeling is that not until recently has the procedure been presented in a convincing manner. Dr. Egan's group does not discount clinical study and examination but recommends a combined effort on the part of all concerned. They state that a diagnosis of carcinoma by mammography must be confirmed by biopsy before radical surgery, even to the exploration of all four quadrants of the breast in the case of a nonpalpable lesion.

They even had a pathologist review his gross specimen and found he had missed a very small carcinoma because he had cut his slices too thick.

We all know that carcinoma of the breast can be cured in a higher percentage of cases if the lesion is small and without metastases, regardless of how the early discovery is accomplished.

COLON CANCER AND INGUINAL HERNIA

The authors report on 107 consecutive male patients with proven carcinoma of the colon and rectum who were treated at a Veterans Administration hospital between 1955 and 1961. During this six-year period 1,334 patients were admitted because of inguinal hernia. Thirty patients had both cancer and an inguinal hernia; of these, 18 first consulted a physician because of symptoms primarily related to the hernia. These symptoms included (1) pain over the hernia, (2) increase in size of a pre-existing hernia, or (3) recent recurrence of a previous herniorrhaphy. These symptoms should lead to suspicion of possible large bowel malignancy because they may indicate early lower intestinal tract obstruction. The authors believe that sigmoidoscopy and barium enema are mandatory in the preoperative study of all patients over 40 years who are being considered for elective herniorrhaphy.

PERSISTENT CARCINOMA OF CERVIX

A pathological review of 83 pelvic exenteration specimens for persistent or extensive carcinoma of the cervix showed the carcinoma to be more extensive than clinically apparent. The urinary bladder was invaded in 61% of the cases and the rectosigmoid in 44%. A poor prognosis was associated with large bowel invasion, but 27.7% of the patients survived for five years. Survival was mostly dependent on finding lymph node metastases. The most characteristic alteration of irradiation was the finding of subintimal foam cell plaques in small arteries, especially near the sites of necrosis.

GENTLE TREATMENT OF CLUBFOOT

Keim and Ritchie have reviewed a group of children with clubfoot in the Shriners Hospital in Winnipeg. The flattop talus is seen usually in the

Continued

treated case of clubfoot, and they demonstrate the "nutcracker" mechanism which tends to crush the talotibial articular surface, causing the flattop talus.

They refer to this mechanism as the "nutcracker effect" and in order to diminish this effect in manipulating an infant with a clubfoot they indicate that the simplest procedure is to loosen the hinge or pivot, the Achilles tendon. This can be done by early tenotomy, and it is a simple, effective procedure that can be done subcutaneously at one level in infants or at the three levels in older children. Maximum correction should not be attempted at one sitting. If the Achilles tendon or deltoid ligament prevents correction, it should be surgically released rather than risk crushing the talus, thereby causing a greater problem than would occur without treatment.

ADVANCED ISCHEMIA, RECONSTRUCTED PROCEDURES OF THE FEMORAL, POPLITEAL AND TIBIAL ARTERIES

These authors performed direct surgery of the femoral, popliteal, and tibial arteries in 206 patients with advanced ischemia of 216 extremities, 100 of these extremities facing immediate amputation. In 50% of the patients the surgical procedure extended distantly into the terminal popliteal, tibial, or peroneal arteries and consisted either of endarterectomy or bypass and thromboendarterectomy. Saphenous veins were used in the bypass procedure or venous patchgraft over areas of reconstruction. The over-all success rate was 82.9%, while the salvage rate in the extremities facing immediate amputation was 72.3%. The degree of improvement in the number of late failures was dependent upon the extent of the disease, particularly in the lower leg vessels. Although pulses were not always restored, even limited restoration of arterial flow was often adequate to halt gangrene, to heal ulcers, and to preserve a useful extremity. The results indicate that arteriography and surgical exploration of the vessels are indicated in all extremities in otherwise operable patients before resorting to amputations. An attempt to restore arterial flow should be made if one or more of the vessels or their equivalent are patent above the middle third of the lower leg. Surgery of the tibial arteries in most cases extended distally to the point of origin of the peroneal and the posterior tibial, and at times even further. Lumbar sympathectomies with removal of the sympathetic ganglion from L-2 through L-5 were performed as an adjunctive procedure in most patients.

This is a provocative article, indicating that even in the face of severe ischemia, diagnostic studies should be done. This is especially true in individuals about to undergo amputation. The authors did not classify the other types of concomitant diseases that might be present, such as diabetes mellitus. However, individuals with such diseases were undoubtedly presumed to be included in this series. The success rate was astonishingly good, even though in 20 patients there were late occlusions three months to five years after the procedure. But even though some had late

Continued

occlusions, approximately 30% suffered only minimal symptoms; therefore surgical procedure was of value. Of the 206 patients, six died immediately after surgery. In four cases the cause of death was not related to the surgery; in two death resulted from myocardial infarction. This points up the fact that these individuals had disease other than in the vessels.

VERTICAL VERSUS HORIZONTAL INCISIONS

From the department of surgery at the University of California in Los Angeles, Halász compares a number of complications and sequelae associated with these types of incisions, using 50 patients in each series.

This was not a double blind study, but the two series were reasonably identical.

It appears that the major complications were those for pulmonary diseases. In the patients with vertical incisions there were ten pulmonary complications as against one in patients with transverse incisions.

It would appear from this study that the transverse incision offers some advantage in diminishing the incidence of pulmonary complications. This is explained on the basis that in the vertical incison a greater number of peripheral nerves are involved than are encountered in a transverse incision; this in turn restricts the adequate ventilation of the lungs and increases pulmonary complication. We should have no fear of deviating from the time-honored ritual of making muscle-splitting incisions, and should have no hesitancy in cutting transversely the rectus sheath and muscle.

The Small Intestine

"Anatomists have divided the small intestine into three divisions. The first eleven inches of its length is the *duodenum.* This comes from the Latin 'duodeni' (twelve) because the early anatomists measured by using their hands as convenient rules and the duodenum is twelve finger-widths in length. The Germans, who are much less patient with classical derivations than we are, called the duodenum *zwolffingerdarm,* which is straight German for 'twelve-finger-intestine.'*

The next eight feet of intestine is the *jejunum,* from the Latin 'jejunus' (empty), because the Roman medical writer Celsus thought it retained no food but merely sent it on. The remainder of the small intestine is the *ileum,* a Latin word that comes perhaps from the Greek 'eilein' (to roll up) because that is what must be done to the small intestine if it is to be made to fit in the abdomen."*

In Chronic Illness: B and C vitamins are therapy

An imbalance of water-soluble vitamins and chronic illness often go hand in hand. STRESSCAPS, containing therapeutic quantities of vitamins B and C, is formulated to meet the increased metabolic demands of patients with physiologic stress. In chronic illness, as with many stress conditions, STRESSCAPS vitamins are therapy.

STRESSCAPS®

FOR PROFESSIONAL RECOMMENDATION ONLY

Stress Formula Vitamins Lederle

Each capsule contains:

Vitamin B_1 (Thiamine Mononitrate)	10 mg.
Vitamin B_2 (Riboflavin)	10 mg.
Niacinamide	100 mg.
Vitamin C (Ascorbic Acid)	300 mg.
Vitamin B_6 (Pyridoxine HCl)	2 mg.
Vitamin B_{12} Crystalline	4 mcgm.
Calcium Pantothenate	20 mg.

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

Until you put a thought in words — sharply and precisely — it isn't a thought at all; it is just a kind of fog rolling around inside the skull. — John Fischer

CARDIAC ARREST AND RESUSCITATION — **By Hugh E. Stephenson, C. V. Mosby Company, St. Louis. Second Edition 1964; 501 pages, $15.00.**

Dr. Hugh Stephenson is Professor of Surgery at the University of Missouri. He has collected in his department a file of over 1700 cases of cardiac arrest reported by some 700 physicians and this book represents the fruits of his studies of this unique collection. Although the first edition is only six years old the advances in this field have been so rapid that the new edition is justified. Every physician who may face the problem of cardiac arrest (and this means every physician) can profit from this book. Cardiac arrest, in the first minute or two, may be a completely reversible complication. To cope with this catastrophe demands a plan of action worked out in advance. There is no time for consultation with the cardio-pulmonary experts; the fate of the victim is decided primarily by the action of the attending physician on the scene. It is with this "first aid" that Stephenson's book is chiefly concerned.

The opening chapter deals with the historical background of cardiac arrest and resuscitation. Ventricular fibrillation has been known since Vesalius' time. Electric current has been used to revive the arrested heart for over one hundred years ago.

In the chapter on the mechanism of cardiac arrest are case reports indicating the universality of the problem throughout medicine. The diagnosis of cardiac arrest is usually made without difficulty: no pulse, respiration, or gasping is present. The patient appears dead. Stephenson warns against diagnostic frills, (including auscultation!) being too time-consuming.

"The delay in making a diagnosis of cardiac arrest is responsible for the bulk of the failures of resuscitation. Until the simplicity of making a diagnosis of cardiac arrest is understood, it is likely that the appalling mortality from episodes of sudden failure of the heart will continue. We still believe that the best rule of thumb is that if there is no palpable pulse and no obtainable blood pressure, both of which have disappeared suddenly, then the diagnosis of cardiac arrest can be made with every reasonable degree of assurance. Let those who disagree assume the burden of proof that under such situations the cardiac activity is sufficient for life. Again let us emphasize, more patients lose their chance for recovery during this crucial period between arrest and diagnosis than from any other aspect of the resuscitative procedure. The time factor represents the crux of successful resuscitation. Few patients can survive after a delay of more than four minutes before artificial circulatory activity is maintained by manual systole. Since the period of reversibility is almost always present in cardiac arrest, it is tragic to allow this period to pass in following time-consuming diagnostic procedures such as searching frantically for a stethoscope or trying to obtain consultation from others. The patient's chance for survival rests with the personnel who are with the patient at the time of arrest."

FITNESS FOR THE WHOLE FAMILY — **Paul Dudley White, M.D., Curtis Mitchell, Doubleday and Co., Garden City, N. Y. 1964, 302 pages. $4.95**

This book has been edited by two men who have had a sincere interest in the health of many of our well-known national figures. It is a compilation of the observations and opinions of 15 or 20 health and exercise consultants or writers who have been interested in physical fitness from a sincere desire to promulgate better health without confusing it with the commercial aspects, as is sometimes done by the faddists.

As Mitchell has so aptly pointed out, "Mankind is currently immobilized by comforts, conveniences, and chemical cures." Dr. Paul Dudley White has stated that the time to prepare for fitness after you have retired is to do it when you are still young. He indicates that physical fitness should become a habit acquired in youth. He points out that it is better to wear out than to rust out, and that the rusting process is much faster when you are inactive.

This book can be recommended to all doctors, and all doctors should be able to recommend it to those patients who wish to introduce physical fitness into their mode of living.

Perinatal Mortality Study

Diabetes Mellitus and Pregnancy*

Case Report

This was the fifth pregnancy of this diabetic, 44-year-old, Rh positive mother. During the pregnancy she was maintained on 50 to 65 units of Lente insulin daily. During the first trimester she had a large buttocks abscess treated with penicillin and tetracycline. On prenatal examinations her urinalyses were always negative for sugar.

The mother was admitted to the hospital at 36 weeks of gestation for observation and management. She was not in labor. On admission, her fasting blood sugar was 104 mgm.%, hemoglobin 11.1 gm.%, white blood count 6,600 per mm.^{3}, and urinalysis negative for sugar and albumin. An admission electrocardiogram showed incomplete bundle-branch block; her blood pressure remained within normal limits. Her Lente insulin dosage was decreased 5 units daily, from 50 units on admission, to 25 units, at which time her urine showed 3 plus and 4 plus glycosuria; the dosage was then increased to 35 units daily. A fasting blood sugar done two weeks after admission was 270 mgm.% (no fasting blood sugars had been done during the two weeks after admission). Also, the fetal heart tones, which had been listened to and recorded daily, were absent two weeks after admission. After four days of absent fetal heart tones, an abdominal X ray of the mother showed air in the biliary tree and umbilical vein of the fetus, with a question of air being present in the fetal heart. Immediately following the abdominal X rays, the mother received two ounces of castor oil orally, which induced labor, and the next morning she delivered an 8-pound, 3-ounce, 21-inch, macerated male stillborn infant at 38½ weeks of gestation. No autopsy was performed on the infant. Two days following delivery, the mother's fasting blood sugar was 375 mgm.%; the Lente insulin was then increased from 35 to 40 units daily.

The mother was discharged one week following delivery with no repeat determination of the fasting blood sugar. Her daily urinalysis on 40 units of Lente insulin varied from 1 plus to 2 plus glycosuria.

Comment

The Ramsey County Perinatal Mortality Study Committee evaluated the care that the mother received during her pregnancy.

1. With diabetes mellitus of such severity, the mother should have been delivered at 36 to 37 weeks of pregnancy, instead of waiting until closer to full term. Concerning pregnant diabetic patients, Reid[1] states: "To avoid fetal and maternal accidents, premature termination, at least by the 36th or 37th week of pregnancy, has been advocated, and there are some authorities who believe that this should be a routine practice. The added maternal risk incurred by this policy is real, however, for it often necessitates delivery by cesarian section. At the same time, as stated before, a large proportion, possibly one third or more, of the fetal deaths in diabetic pregnancies occur during the last few weeks without warning or demonstratable cause. What is more disturbing is the fact that in these patients there is no detectable clinical toxemia, and their diabetes is metabolically well controlled." Thus, in the present case, even though the diabetes was not ideally controlled, the fetus still may have died before full term even under ideal insulin control.

2. The medical care of the mother's diabetes in this case was not adequately controlled. With a normal fasting blood sugar obtained on 50 to 65 units of Lente insulin daily, her dosage should have remained at that level, rather than lowering the dosage to 25 units of Lente insulin daily with resulting 3 plus and 4 plus glycosuria and even a fasting blood sugar of 270 mgm.% when the dosage of insulin was raised to 35 units daily.

---

*Ramsey County Perinatal Mortality Study Committee.

Continued

Furthermore, the mother should not have been discharged home with 40 units of Lente insulin daily when she had a fasting blood sugar of 375 mgm.% along with 1 plus to 2 plus glycosuria on 35 units of Lente insulin daily.

With proper medical care of severe diabetes mellitus in pregnancy, along with induction of labor at 36 to 37 weeks of pregnancy, it is hoped that more infants born to severely diabetic mothers can be salvaged.

Ten Commandments to Prevent Alcoholism*

PHYSICIANS should instruct their patients to follow these ten rules to avoid the development of alcoholic dependency:

1. Never take a drink when you "need" one.
2. Sip slowly and space your drinks: the second drink 30 minutes after the first; the third an hour after the second; and never a fourth.
3. Dilute alcohol. Have a long, weak drink — never on the rocks, never straight and never, never out of the bottle!
4. Keep an accurate and truthful record of the amount and number of drinks you take.
5. Never conceal the amount of alcohol you drink. Instead, exaggerate it.
6. Do not drink on an empty stomach.
7. Stop drinking on signal. The signals are: "luncheon," "left office," "on the way home," "before dinner," "before bed," "meeting people," "celebrating" and "to get me through." Substitute something in place of alcohol at these times, such as a big cup of hot, strong tea before dinner to refresh and energize (mountain climbers drink tea, not alcohol).
8. When tired or tense, soak in a hot tub and follow with a cold shower.
9. Never take a drink to escape discomfort, either mental or physical.
10. Never, never take a drink in the morning, thinking it will offset a hangover.

Avoid alcohol dependency as you would the plague. It is most insidious and unless you are very careful, it will steal up without your knowing it.

Derivatively Speaking

Carbuncle derives from the Latin *carbunculus* (a little coal), diminutive form of *carbo* (coal). Red stones (the ruby and the garnet) were called carbuncles because they resembled glowing coals. Later the term carbuncle was used to designate a red spot of inflammation on the surface of the skin, originating in the tissues and looking and feeling like a glowing coal.

The past always looks better than it was; it's only pleasant because it isn't here.
— Finley Dunne

History of Medicine

Harvey Cushing — Part II*

(1869-1939)

Since the life of Harvey Cushing was portrayed in this department last month, we have received permission to add some personal reminiscences by one of Doctor Cushing's former pupils at Johns Hopkins. Carl W. Rand, M.D., of Los Angeles, furnishes some interesting anecdotes about his great teacher.

"I do not remember exactly when I first heard of Doctor Cushing, probably very early in my student days at the Hopkins; but certain it is, that stories of this gifted, energetic, young brain surgeon were impressed upon me before I had entered upon my clinical years . . . My formal introduction, however, came most unexpectedly in my junior year. Doctor Cushing gave an elective course in dog surgery, which proved to be the most popular in the school, and lucky indeed were the students who were enrolled. It was held in a small brick building — the Hunterian Laboratory — which was about as crude and crowded as that in which the "great John" had once worked. But with Doctor Cushing passing from group to group the class was on the *qui vive,* and many a trembling incision and faltering stitch were made under his penetrating eyes. He was a master surgeon, and would tolerate no mediocre performances. On the day in question it had fallen my lot to take the part of anesthetist, the "patient" being an unusually large and somewhat vicious dog, whose teeth were prognathic, and who did not take kindly to the idea of being put to sleep. And when one considers that he was strapped on his back on a hard table with his legs pinioned down, one could hardly blame him. The cone, in which rested the sea sponge upon which the ether was poured, barely covered his dark muzzle, and I was having a desperate struggle to get him under. During a lull in the fracas, I suddenly became aware that Doctor Cushing was standing directly behind me. I tried frantically to suffocate the "patient" before being reprimanded, but to no avail. Finally with a very red face and forced grin, I turned apologetically and said in a hesitant voice: "He's a pretty big dog and I can hardly get the cone over his nose." To which Doctor Cushing replied with a toss of his head and a pat on my shoulder, — "Don't blame your golf balls," — and walked on. Whether or not he appreciated the humor of the situation, I never knew; I believe he did.

My next intimate experience with him occurred two years later, when I was an intern. By then we had learned that "Cushing patients," especially those harboring brain tumors, were to be most closely watched. Their every sign and symptom must be recorded in minutest detail. It happened that a man with high intracranial pressure, secondary to a suspected tumor, came under my care. One afternoon, on going into the ward, I noticed that he was cyanotic and gasping for breath. As I stood by the bed he stopped breathing, although his heart continued to beat. Instinctively I climbed upon the bed and started artificial respiration, impulsively telling a nurse to send for Doctor Cushing. Upon arriving, he took in the

Continued

---

*See Minnesota Med 48:283, 1965.

situation at a glance, told me to "carry on" and ordered the surgery to be set up at once. With the patient finally in the prone cerebellar position on the table, he deftly shaved a patch of hair, made a quick incision and trephined the skull. He then carefully introduced a ventricle needle directly into a cerebellar cyst, and yellow fluid escaped in a parabolic stream. It somehow reminded me of blood letting. How he knew the exact location of the lesion, for he had had scant time to examine the patient, is still a mystery to me. In a few minutes spontaneous respiration was again established and my tired arms were given rest. A few days later I watched Doctor Cushing with his deliberate and meticulous technique, remove a large cystic astrocytoma from this same patient. The man recovered and was given many years of useful life.

During the World War I had tried repeatedly to secure detachment from the backward area in which I was stationed, in order to see active work at the front. All efforts through military channels failing, I wrote a personal letter to Doctor Cushing, who was then Chief Neurosurgical Consultant in the American Expeditionary Forces, asking transfer for duty under him. Within a week, in some mysterious way, I received orders to report at a certain camp, where a neurosurgical operating team was awaiting me. Doctor Cushing had arranged it by some direct method known only to himself.

His methods of treating head wounds at the front had proved revolutionary and many lives were thereby saved. I think he took deep satisfaction in visiting his various 'teams' who were carrying out his operative technique. On one round of inspection he happened into a tent hospital and found me in the act of removing a piece of shrapnel from a soldier's brain. I became aware of him standing behind me and felt a good deal as I had when he watched me trying to anesthetize the dog years before. I even wondered about my 'golf balls'; but peering over my shoulder he said quietly 'good work,' thus dispelling my apprehensions."*

History of Medicine in Wright County*

Dr. Suttan, according to an item from the Howard Lake correspondent in the *Delano Eagle* of October 16, 1884, was building a large addition to the Dr. Ball Building. Nothing else is known of him, not even whether he really was a physician.

Wilfred (P.) Tessier, a graduate of the College of Physicians and Surgeons, Minneapolis, in 1887 may have practiced in Wright County for a short time in that year. A news item (*Delano Eagle,* July 28, 1887) tells that "Dr. Tessier of Minneapolis is locating here. We understand he formed a partnership with Dr. Mignault" and in October (*Delano Eagle,* October 20, 1887) we learn that "Dr. W. P. Tessier has started for Annandale where he intends to locate."

This is all the information about him that could be found.

A married woman's as old as her husband makes her feel. — Arthur Pinero

Special Report—

*The General Practitioner and the Price of His Recovery**

H. P. VAN CLEVE, M.D.
Austin, Minnesota

THE GENERAL practitioner is disappearing from the American scene. Perhaps we should merely celebrate his demise as a needless vestige of an outmoded culture.

I want to present to you two case histories which perhaps will illustrate for you the strengths, the weaknesses, and the problems confronting the general practitioner today.

Case Report

The first case is that of a forty-one year old housewife who came to see me complaining of chest pain. In the way she presented her story it was obvious that she was concerned about her heart. At forty-one she certainly was not a likely victim of coronary artery disease and the description of her pain also did not point in this direction. However, she was overweight and somewhat hypertensive. Physical examination revealed no other abnormalities.

I had known this patient well for several years. She had four children, aged 5, 11, 13, and 15. Her husband was a repairman, and the family economically was caught in that common squeeze where their income did not quite meet what they felt to be their needs. At various times I had seen all members of the family and had made calls to their home. She was much like a mother hen, deeply concerned over her brood, but not much of a housekeeper. I had cared for one of her children just after the family had moved to town. The child had had extensive medical care in a large city where many examinations had failed to demonstrate specific disease but borderline findings indicated something might be present. A letter from the pediatrician had read, "We have never arrived at a definite diagnosis but felt that possibly a mild glomerulonephritis was the best explanation for her elevated sedimentation rate and urinary findings." Maternal anxiety and medical uncertainty had resulted in six months loss of schooling for the child, most of which was spent in bed. At that time, after much discussion, the mother had accepted my recommendation that it was time to fish or cut bait and we should try getting the child up. We did and all went well. (Eleven years later the child is still well; the original illness is still unexplained). So I know this patient and her family quite well.

I sensed her pains were functional, but what had caused them? I said, "I've known you and your family for some time and yet I know very little

---

*This paper was presented on May 8, 1964, at a seminar at the Ambassador Motel, Minneapolis, on undergraduate medical education held under a grant from the Hill Family Foundation by the Clinic Directors Committee of the Medical School. At this time Doctor Van Cleve was serving for a one-month period as an assistant professor in the Comprehensive Clinic Program of the Medical School under a grant from the Hill Family Foundation. His responsibilities centered about teaching personal medical care to the senior medical students in the outpatient clinic.

Continued

about you personally. Tell me something about yourself." With no more encouragement she told of a father that had deserted her mother when she was an infant. Her mother had remarried and she had had a happy childhood and looked on her stepfather with the love of any child for her own father. Several months before coming to see me, her true father had written her and told her he had remarried and that his second wife was dying of cancer. Would she please come and help him take care of her? It was a real sacrifice for her to go, but she went. Shortly after she arrived, her father showed his true colors again and again walked out, leaving her to care for a woman whom she had never known while the woman gradually succumbed to cancer. On completing her story, she paused a moment and said, "I don't know why I am burdening you with my troubles." I told her, "I asked you to." After still another pause, she looked up and asked, "What has this got to do with the pain in my chest?" I replied, "I think it has a lot to do with the pain in your chest." She got up, tidied up her appearance for her departure, hesitated at the door, looked at me and said simply, but with much feeling, "thank you," and departed. In the nine years since this episode, I have seen her many times, sometimes for herself, sometimes for her children. She has had occasional episodes of anxiety, mundane problems such as sore throat, and so on, but never has she had a recurrence of her chest pain.

I give you this case history because it illustrates some very cogent advantages of continuing medical care, the kind of care most readily given by a family physician. Let's look at the way this same patient would have been treated at a major medical center. A more detailed history — medical history, that is — would have been obtained. A complete physical would have been done. It is most likely she would not have escaped without some basic laboratory tests, a chest X-ray, and an electrocardiogram. Her painful, personal story would probably not have been elicited. I am sure the same diagnosis would have been reached by the physician and probably would have been conveyed to her in some such manner as "There is no evidence of trouble with your heart. Your pains are related to your emotional problems." The patient is left with many doubts such as "If the doctor is so sure, why did he do all those tests? Maybe he just couldn't find out what is wrong." If the patient had been referred to a psychiatrist, she probably would have ended up with a true understanding of her emotional problem, but meanwhile she would have spent a good deal of money the family could ill afford. She also would now have the feeling of guilt concerning this expenditure and, I believe, some increased insecurity to think that she could have been so "shook," so to speak, that all this had to be done to get her straightened out.

I am not very proud of the second case. In fact, it is quite painful to me to give it to you. However, as the first case illustrates the family physician functioning well, this case shows the reverse and illustrates the shortcomings of the family physician, shortcomings partly of his own making, and partly due to responsibilities forced upon him which he rather would not bear.

Case Report

A nine month old infant, was admitted as an emergency because of moderately severe dehydration. I was on emergency call and was not the usual physician for the family. History revealed the infant had had vomiting and diarrhea of several days duration. During this time his diet had consisted mostly of boiled skim milk. He was irritable and his temperature was 102° rectally. Examination revealed no other significant pathology. Having drifted away from doing much pediatrics, it has long been my policy to get pediatric consultation on all pediatric admissions. Our pediatrician had left the community and pediatrics shortly before as he could not stand all the calls and the continuing pressures of being a family doctor to children. It was a weekend and no other consultation was easily available. The problems of rehydrating the infant did not seem too complex. A standard text was consulted and fluids started accordingly. The child's temperature dropped overnight and he looked much better but was quite lethargic. Urine output was good. Fluids were continued at a rate suggested by the text. About twenty hours after admission the child suddenly convulsed and stopped breathing. Prompt efforts at resuscitation failed. An autopsy revealed cerebral edema. A recapitulation of the case showed that in spite of administration of fluids by a standard recent text, fluids actually were almost double what were recommended by other authorities and this undoubtedly had resulted in the cerebral edema and death.

I believe this sad case illustrates some of the basic problems confronting the family physician today. All of us in a major emergency may be forced to render care we were supposedly trained to handle but which we no longer can give with great facility. For example, if the Twin Cities were hit by an atomic bomb, most if not all of you who survived would find yourselves doing general practice, that is, taking care of all who came, regardless of their problems, in the best manner in which you were able. I am sure even the thought of learning to function in such a role is quite disquieting. While it is unlikely this will ever happen to you, to some degree it happens to the general practitioner frequently. When all is going smoothly, he handles those problems which are well within his scope of practice and refers those he is unsure about to someone else. All too often he is confronted with having to function in areas in which he feels limited because, firstly, no readily available consultant can be called in, and secondly, the problem doesn't appear to be serious enough to justify moving the patient a long distance to another medical center.

These two cases describe the general practitioner both when he is at his best and at his worst. Obviously his education must change so that he can function most of the time at his best and never, if that is possible, as illustrated in the second case. How? Well, here is what I believe! If the general practitioner is to survive, and survive he should, he must be educated better, he must be educated differently, and he must continue to be educated until the day he quits. He will not survive so long as his colleagues feel that he is a second class physician. His role and his preparation must be such that he no longer needs to look at the specialist and say to himself, "Anything I can do you can do better." He must be so trained that he can look the specialist in the eye and say, "Go ahead and treat disease, I'll treat people."

Training the General Practitioner

Dr. Dicks, an Englishman, writes the following about the present training of the general practitioner:

"I hold that the discouragement of the G.P. begins from the day he enters the hospital as a clinical student. The social and scientific prestige structure of the teaching hospital is created by the demigods of specialisms, who, even if modestly endowed, can still lord it within the kingdoms of their own firm and wards. . . . The student will tend to identify himself with these teachers, hoping he will be like them, have their skill, and emulate their practice and their manner, perhaps also their pomp and worldly success. The 'ideals' set before future G.P.'s are thus not older, wiser G.P.'s, but a series of figures of supposedly superior ability who have each mastered some special skills, to none of which our student can hope to attain.

"In fact these mighty consultants do not teach the G.P. more than a fraction of what he finds it useful to know. Yet, owing to identification and prestige, he still feels he has learned 'his medicine' and 'his surgery' from them and ought to be very grateful. Actually, what he has seen impressively in action has been the full-scale clinicopathological method applied to 'good teaching material — i.e., to patients with well-marked structural or biochemical change, where by a series of well-judged tests, recorded on charts of many hues, the right diagnosis fell into the team's lap. The image of good doctoring was that of the 'great white chief' performing miracles of mechanistic skill on a dramatic, perhaps catastrophic, but rare case, while the dull sort of case, whose pain did not fit in, was perhaps half-jokingly referred to 'our psychiatric colleague.' Interest in the common disease and worries of human beings was seldom shown, while the psychiatrist's field was too remote and creepy for sound practical men."[4]

Dicks says further: "I hold that the good general practitioner is the pivot of all adequate personal, friendly care for sick people and of preventive watch over the health of families and work groups. He could be, and often is, adviser and counsellor in matters often far removed from what is taught in hospitals but close to human health and happiness. To fulfil this role he ought therefore to have the opportunity to cultivate from the beginning of his medical studies the widest vision of human beings and their manifold troubles. This implies that from the first he must be introduced to the concepts of personality and culture-pattern, and not only to theories about chemicobiological mechanism or, at best, organism.

"To sustain his orchestrating function in relation to his client's condition, he needs to know enough about special techniques of diagnosis and therapy to decide when to call

Continued

in a technician (surgeon, psychiatrist) and how to evaluate the latter's advice. He need not be a master of any of these special crafts. His is the synthesising, presiding role — a role which the general hospital physician is apt to arrogate to himself, with far less claim to adequate knowledge of the patient."[4]

This indeed involves some basic changes in our current concepts of physician education. Dr. Dicks then proceeds to make many excellent recommendations for changes both in premedical as well as in medical education. To list his recommendations would make this paper too long but I do want to give you his introductory remarks:

"In attempting the following outline of education in a broad human medicine, I make the following assumptions:

"That we really desire, in the general medical course to produce a general practitioner, rather than offer a course of bits and pieces, vaguely making propaganda for the superiority of hospital practice.

"That this training should prepare *all* doctors, but especially general practitioners, to be competent to handle the psychosocial relations as well as the physical factors in the promotion of health and efficiency in individuals and groups, and in the reduction of human suffering.

"That specialization is and will remain a postgraduate task.

"That, training matters apart, the conditions and status of general practice will be so altered as to remove the present negative incentives which operate against the entry of highly gifted doctors into it by promoting the reforms advocated by Collings — e.g., grouped practices, finance, access to hospitals, and integrating responsibility for patients."[4]

No amount of polishing the present vehicle of medical education and practice will draw students into general practice. We need a new car. What is the alternative? Where will the present vehicle take us? Let me give you a few figures, a few quotations, and a Jacob Marley peck into "Christmas yet to come."

As you know, the general practitioner is truly disappearing from the American scene. In 1931 general practitioners constituted 71 per cent of all physicians in this country. In 1962 this percentage dropped to 27 per cent.[1] Only 20 per cent of medical school graduates today indicate they will go into general practice. An unknown percentage of these — but a sizeable one — will leave general practice after varying periods of time for specialty training. If these trends continue, the general practitioner will not be a significant factor in the practice of medicine 25 years from now.

T. F. Fox, an Englishman, made a survey of American medicine, its present and future, and wrote a lengthy treatise appearing in the "Lancet" for April 2, 1960. He made many interesting observations and some very pointed comments. Among them he says:

Replacing the General Practitioner

"Perhaps I am wrong, but I should guess that in the prevailing culture of the United States, the independent personal doctor is going to be specialized out of existence, and that within a few decades medical care will mostly be based on the hospitals."[5]

If the personal physician is to disappear, I would suggest that he will be replaced in any one or a combination of three ways:

1. He may be replaced by a hospital type practice as suggested by Fox. This is largely extant in England today.
2. He may be replaced by an internist-pediatrician team.
3. He may be replaced by technicians as is the case in Russia today.

The first two of these are already taking place in part. All three have glaring faults. George James, Commissioner of Health for New York City, writes "The executive with a polished walnut desk can usually arrange to leave his office for an hour to see a private physician. The unskilled worker in the shipping room, newly arrived from Puerto Rico, cannot so easily take the hour, and he has no private physician anyway, so what he may need is several four hour periods of waiting in each of a long series of specialized clinics." Thus, he does not use such care even if it is free. Instead, he will tend to utilize hospital emergency rooms and get "episodic, inadequate care."[7]

Hospital Practice

This states the resistance of the affluent to hospital practice and the inability of the marginally employed to avail themselves of such services. In addition, hospital practice for the 45 per cent of our people living outside the big urban areas is a complete impossibility. But this may come, nonetheless.

Internist-Pediatrician Team

The internists and pediatricians have already clearly indicated their lack of interest in filling the role of the general practitioner. Only 25 per cent of the decrease in the general practitioners has been replaced by internists and pediatricians. In addition, these have gravitated to the urban areas whereas the distribution of the general practitioner has remained distributed as before. As mentioned, in my city of 25,000 people, we lost our pediatrician. He left the practice of pediatrics completely for a job that freed him from the pressures of being a general practitioner for children, even though this involved a 50 per cent cut in his income.

Technicians

I have been given to understand by one of the staff just back from the west coast that there was much talk about the third alternative, namely the training of technicians. I have found no one who has dared to suggest this in writing. I have found many who have decried the possibility. Fox says: "When personal medical care is abolished, it is sooner or later reinvented. Thus, even under the Soviet system, the Russian leaders have personal physicians. It is the natural and sensible thing to do, and they can afford to do it. So should we."[5]

The Russian masses, you will recall, depend on technicians.

The Too Busy General Practitioner

There is one other fault of the general practitioner which I should discuss. He is much too busy. He has been unable to change the ecology of his society.

The average patient sees a physician three times as often today as he did 30 years ago. Remember also that there are only about one-third the number of general practitioners as thirty years ago and our population has doubled. This means that the average general practitioner today must see 25 or more patients per day plus innumerable telephone calls. He finds that either he cannot give the time he wishes to his patients or he must refuse care when called upon. He finds himself in a hopeless bind.

His public image has been severely damaged by refusing care in some cases or by insisting upon seeing the patient in the office because of lack of time. Any good practitioner today finds himself in this dilemma.

If he cuts his practice by refusing care, he is criticized. If he raises prices to cut his practice, he is criticized (plus the fact it doesn't work). Most drift into a sad third alternative, namely that of spreading himself so thin that he ceases to give satisfactory personal care. At this point his practice automatically starts to limit itself. This fault, that of being too busy, can only be remedied by graduating more general practitioners. Otherwise, it will get worse, not better. Freed from the tremendous volume of patients to see, the general practitioner could then function in the way he should function, "looking after people as people and not as problems."

Conclusion

In conclusion I would like to quote at some length, Iago Galdston. At the conclusion of his article entitled "The Birth and Death of Specialties," he comes to a conclusion different from that of Fox. He states:

"What I mean to convey is this: the future of medical service is not to be envisaged as a continued refinement, as well as increase, in the specialties, with the consequent parceling out of the patient to a host of men, who will care for him and treat his illnesses. I think rather that within two generations, that is before the second millennial year is reached, medicine as a science, and medical service perforce, will have undergone a revolutionary change, in many respects as profound as that effected by the rise of bacteriological

Continued

sciences. This revolution will not be brought about by the economic, legislative, or social manipulations of well-meaning men but by the maturation of those knowledges and intelligences embraced in physiological, and in ecologic, medicine. Unless global disaster puts an end to civilization and to science, the eventuations I have sketched are to my mind inevitable.

"I am conscious of the fact that in my presentation I have been somewhat light in my treatment of present-day medicine, including its specialists. I may have thus given you an erroneous idea of the esteem in which I hold contemporary medical science with its practitioners. I deem them both of the highest order. Were I grievously sick and had I the choice to be sick in any age in history, from the time of Hippocrates to the present, I would choose none but the present. For at no time in the history of man has the practitioner of the healing art been as tutored in the skills and as well armed with as great a multitude of means to fend against the ravages of sickness, and even more against pain and suffering as he is today.

"But as I have argued and as is clear to all thinking men, the treatment of disease is not the equivalent of the promotion of health, and well-being — and specialists treat disease.

"I am not so sanguine in my hopes for mankind, nor so naive, as to believe that man will ever so manage his life as to have no need for 'cures' and for the specialist who ministers them. I can envisage an attrition in specialties and specialists but not their total elimination from the medical scene or corps. It is only that I can see the future of medicine as lying in directions other than greater and ever greater specialism.."[6]

The doctor in active general practice today is making great strides at keeping abreast of new medical developments. He does need continuing medical education. The program in which I have been involved, namely teaching personal medical care to the senior medical students, has, I hope, been helpful to the students for it has certainly helped me to broaden my horizons and to develop an increased awareness of the rapid growth of medical knowledge. I believe an expansion of this program plus other new techniques would be tremendously helpful in keeping the general practitioner not only well informed but also an active, participating member of the medical family. But all such efforts will not be enough if those of you in medical education do not succeed both in modifying the educational climate from which the general practitioner must come, and in modifying his training program so that he may function with skill and pride as a knowledgeable family physician. If this cannot be done, new students will not be attracted to general practice and the general practitioner will ultimately disappear. The American public will be the loser.

Addendum

This paper has dealt with the problems of education of the general practitioner. It has not dealt with the many socio-political aspects which also affect his future, such as the general practitioner's role under socialized medicine, should such a situation evolve. Anxiety over his status as a general practitioner in a socialized medicine milieu was the reason most frequently mentioned by students for avoiding general practice.

Health and Accident Insurance

"How much health and accident insurance should I carry?"

In undertaking to answer that question, it is important for the Doctor to remember that health and accident insurance is disaster income, and that it is neither necessary nor prudent to carry insurance equal to his earned income. It is essential merely that he have enough income to assure the basic necessities for himself and his family and to meet any fixed obligations to which he is committed.

It is much more important to have indemnity for long enough periods. Health and accident insurance should be based on need, and should not be carried in excess of that need.

After considerable study of the problem, Professional Management Midwest has adopted the following basic principles regarding health and accident programs.

Amount of Coverage

Monthly coverage should consist of a minimum $400 per month, plus $50 per month for each dependent including the Doctor's wife, and an amount equal to his fixed monthly financial commitments. For example, if a Doctor has a wife, three children and mortgage payments of $150 per month, he should carry at least $750 monthly protection. In making this computation, the physician should make an adjustment for income from outside sources.

Types of Contract

It is our recommendation that at least 50 per cent of the coverage be high-quality, permanent, individual policies with reputable companies. Needless to say, these should be noncancellable and guaranteed renewable to age 65. Thus, at least half of the program will be assured of permanence.

The remaining half of the program should consist of high-grade group contracts. Though semi-permanent, these policies are contingent upon the Doctor's continued membership in the group and on the continuation of the relationship between the group and the insurance company.

Indemnity Periods

Since we believe in long-term catastrophic coverage, as opposed to short-term protection, and since most Doctors have cash and accounts receivable to carry them for at least 30 to 90 days, we recommend the following indemnity and elimination periods.

Sickness: Indemnity should start the thirty-first or sixty-first day, and should be payable for a maximum period of seven to ten years.

Accident: Indemnity should start with the first day of disability and should be payable for life. Since most good policies pay from the first day, no elimination period is recommended.

Health and accident insurance is a highly competitive field, and there are many bad, as well as good, contracts being written today. As with most other goods and services, it should be borne in mind that one gets what he pays for. The day one becomes disabled, it will be too late to discover that he has purchased a virtually worthless policy. Thus, with the aid of his insurance advisor, the physician should carefully evaluate his needs and each contract's provision before he buys.

The Relative Value Schedule of Hammurabi

Hammurabi, king of Babylon about 2240 B.C., was famous as a legislator. He developed a code of ethics, laws, principles, consisting of 282 paragraphs which were engraved on a stele* of black diorite* which is now in the galleries of the Louvre in Paris.

Some of the laws with relation to doctors are embodied in paragraphs 215 to 224:

If a physician has healed a man's eye of a severe wound with a bronze instrument or has opened a spot in a man's eye with a bronze instrument and so heals a man's eye, he is to be paid 10 shekels for his work. If the man is a nobleman, the physician will receive 5 shekels of silver and if the patient is the slave of a free man, the master will give the physician 2 shekels.

For a broken limb or for a sick bowel, the patient is to pay the doctor 5 shekels* and if the patient is the son of a nobleman, 3 shekels will be the fee.

If the doctor has been unfortunate and the man's eye is destroyed at the hands of the physician, then the physician's hand is to be cut off.

Editor's Note: I guess we're making progress.

Better Service, Doctor?

I DON'T FEEL GOOD!

Yes, Blue Shield wants to serve Minnesota doctors even better than it has. But we need your help.

When reporting claims, list symptoms for diagnostic laboratory and X-ray services ONLY. We do not need symptoms for any other service.

And, there must be a *direct* connection between those symptoms and the tests.

Payment for incomplete reports might be delayed . . . or rejected. Help us help you!

June 20-24, 1965
114th Annual Convention

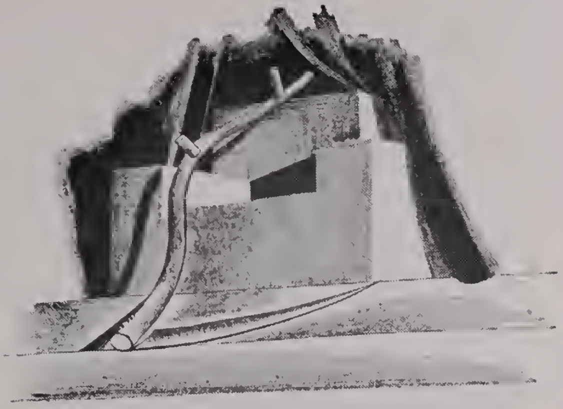
Come to New York City June 20-24. Be part of tomorrow's medicine and participate in the year's most extensive scientific meeting.

The excitement of America's largest city is available to you at the best time of the year, as you relax and review—in air conditioned comfort—the most recent developments in general practice and all the specialties.

- Six general scientific meetings
- 23 medical specialty programs
- 700 scientific and industrial exhibits
- Lectures, panel discussions, motion pictures and color television

Plan to attend—continue your postgraduate education.

See JAMA May 10 for complete scientific program—forms for advance registration and hotel accommodations.



In Memoriam

Whether your time calls you to live or die, do both like a prince.—Sir P. Sidney

ARTHUR W. GARBRECHT, M.D.

Dr. Arthur W. Garbrecht, 71, St. Paul physician, died April 8th. He was born in Berlin, Germany, and received his degree in medicine from the Friedrich-Wilhelm University in Berlin.

Having practiced medicine in St. Paul since 1924, Dr. Garbrecht was a member of the Radiological Society of North America, a staff member at Riverview Memorial hospital, member of the American Medical Association, Minnesota State Medical Association and the Ramsey County Medical Society.

He is survived by his wife and daughter.

DOROTHY W. HUTCHINSON, M.D.

Dr. Dorothy W. Hutchinson, 66, a physician at Glen Lake Sanatorium for thirty-five years, died April 2nd while vacationing in Florida.

She was a member of the American Medical Association, Minnesota State Medical Association, Hennepin County Medical Society, American Thoracic Society and was active in the Planned Parenthood of Minneapolis.

She is survived by her husband, Dr. Robert W. Browne, a retired dentist.

ROLAND EDWARD NUTTING, M.D.

Dr. Roland E. Nutting, 66, prominent pediatrician and member of the Duluth Clinic, died March 26th. He was born in Clarissa, Minnesota, and received his medical degree at the University of Minnesota.

He was the first Minnesota state chairman of the Child Health Organization of the American Academy of Pediatricians, a past chief of staff at both St. Luke's and St. Mary's hospitals, chairman of the board of trustees of the Duluth Congregational Fellowship, and a member of the American Academy of Pediatrics, the American Medical Association, the Northwestern Pediatric Society, the Interurban Academy of Medicine, the Minnesota Pathological Society, the Minnesota State Medical Association, the St. Louis County Medical Society, the Alumni Association of the Mayo Graduate School of Medicine and Alpha Kappa Kappa medical fraternity.

Dr. Nutting is survived by his wife and two sons.

ADOLPH G. LIEDLOFF, M.D.

Dr. Adolph G. Liedloff, 87, retired Mankato physician, died March 20th. He was born in Mankato and graduated from the University of Minnesota Medical School.

He was responsible for halting the typhoid epidemic in 1908 in Mankato and also served as county health officer and county coroner. Dr. Liedloff was a past secretary of the Minnesota Valley Medical Society and the Blue Earth County Medical Society, a past president of the Blue Earth County Medical Society and past vice president of the Minnesota State Medical Association.

He was a member of the Minnesota Trudeau Society, Minnesota Heart Association, Blue Earth County Public Health Association, American Medical Association, 50 Club and Life member of the Minnesota State Medical Association and a former director of the local district of the Minnesota Department of Health.

He is survived by his niece, Mrs. John Castle, of Delaware.

PHILIP SHOWALTER HENCH, M.D.

Dr. Philip Showalter Hench, 69, former member of the Mayo Clinic staff, world-famous authority on arthritis, pioneer in the clinical use of cortisone and co-winner of the Nobel Prize in Physiology and Medicine in 1950 for his work with that hormone, died in Jamaica, on March 30th. He was born in Pittsburgh, Pennsylvania, and graduated from the University of Pittsburgh Medical School. He became a fellow in medicine in the Mayo Graduate School of Medicine in 1921.

Throughout his life, Dr. Hench received many honorary degrees from colleges throughout the world, and for many years was considered one of the leaders in American rheumatology, being one of the founders of the American Rheumatism Association of which he was a past president. Throughout his lifetime, he was honored by practically every country and organization in the world. His memberships in societies and associations were numerous, and the offices he held were many.

He is survived by his wife, two daughters, and two sons, one of whom is Dr. Phillip Kahler Hench of LaJolla.

Physician's Diary

He alone has lost the art to live who cannot win new friends. — Sir Weir Mitchell

Dr. H. J. C. Swan, Mayo Clinic physiologist specializing in cardiovascular diseases, and **Dr. Patrick A. Ongley**, Mayo Clinic pediatric cardiologist, received the Susan and Theodore Cummings humanitarian award from U. S. Surgeon General Luther Terry, at the American College of Cardiology's annual meeting in Boston. The Mayo specialists were among fifteen American physicians honored.

* * *

Dr. Wesley W. Spink, University of Minnesota professor of medicine, has been named to a newly formed medical advisory board that will aid the Food and Drug Administration in its safety program for drugs and therapeutic devices.

* * *

Dr. Byron U. Musa was the recipient of the Watson Award, presented annually by the Minneapolis Society of Internal Medicine to a physician in graduate clinical training at the University of Minnesota Medical School.

* * *

Dr. Homer H. Hedemark of Ortonville has been elected a fellow in the International College of Surgeons, and **Dr. Anatol Lysyj** of Minneapolis was installed as a fellow of the American College of Obstetricians and Gynecologists.

* * *

Dr. Clarence W. Moberg of Detroit Lakes has been selected as one of the one hundred outstanding Minnesotans to be recognized with a "Republicans' Care" award. This award is given to persons who have contributed much of their time and energy to meeting human needs and working toward the betterment and growth of the communities in which they live.

* * *

Dr. James C. Cain, consultant in internal medicine in the Mayo Clinic, has been elected a member of the Board of Governors, representing Minnesota, of the American College of Physicians.

* * *

Dr. E. G. Hubin has been awarded the Sandstone County Man of the Year Award by the Chamber of Commerce of Sandstone.

NEW LOCATIONS: **Dr. William Martin**, Duluth internist and cardiologist, has accepted a position in Dayton, Ohio . . . **Dr. Robert Witter** and **Robert Murtaugh** of Wadena have dissolved their partnership and set up individual offices . . . **Dr. Phillip J. Parker** of Staples will practice medicine in Fertile . . . **Dr. E. C. Bayley** and **Dr. D. W. Sontag** plan to construct a new professional medical building in Lake City . . . **Dr. B. R. Briones** of Minneapolis, joined the Drill Clinic of Hopkins.

* * *

Doctors **Keith E. Holley, Andrew G. Engel, Franz J. Hallermann, Leo F. Black, David R. Sanderson, Raymond A. Lee** and **John T. McCall** have been appointed to the staff of the Mayo Clinic, Rochester.

* * *

Dr. Terrell F. Yeager of Anoka has been installed as a Fellow of the American College of Obstetricians and Gynecologists.

* * *

Dr. Arthur H. Bulbulian, director of the Mayo Medical Bureau, will be guest of honor at the fourth annual Banquet of the Golden Plate at Dallas, Texas. The banquet is "A Salute to Excellence" limited to fifty outstanding persons in this country and abroad in the fields of science and humanities.

* * *

The new officers of the Worthington Municipal Hospital are: **Dr. Arthur Amick**, president; **Dr. Edward Seisler**, vice president; and **Dr. B. J. Desai**, secretary-treasurer.

* * *

At the April meeting of the staff of the Glencoe Municipal Hospital the following officers were elected for the coming year: **Dr. C. W. Truesdale**, Glencoe, president; **Dr. John J. Smyth**, Lester Prairie, vice president and **Dr. Donald Navratil**, Glencoe, secretary-treasurer.

* * *

Dr. Tracy E. Barber, Austin, was elected secretary of the Industrial Medical Association at the Association's Fifth Annual Meeting recently in Bal Harbour, Florida.

* * *

Dr. Rafael Fernandez of the Anoka State Hospital medical staff was recently certified by the American Board of Internal Medicine as a diplomate in internal medicine.

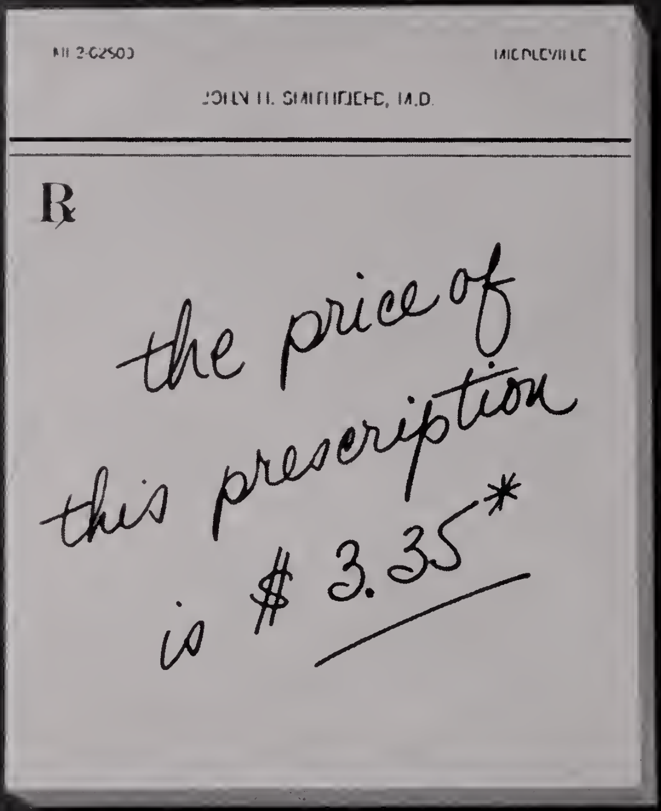
GENERAL PRACTITIONER WANTED: Lamberton, Minnesota. Nearly new Sears Roebuck Foundation designed clinic available. Excellent school, churches and community. Call or write: Wallace Nelson, Lamberton, Minnesota, 56152, Telephone 752-7717.

Continued



How much would it be with no manufacturer's profit?

$2.09? $.93? $3.18?

Somewhat amazingly, $3.18 is correct. Even if you eliminated pharmaceutical manufacturer's net profit, your patient would pay only about 17 cents less for the average prescription—hardly a deciding factor in having it filled. Of course, this assumes that pharmaceuticals could continue to be available without profit (where do new miracle drugs come from, if not profit?).

American pharmaceuticals today may well be America's biggest bargain.

Pharmaceutical Manufacturers Association/1155 Fifteenth Street, N.W., Washington, D.C. 20005

This message is brought to you as a courtesy of this publication on behalf of the producers of prescription drugs.

Initial salary $18,000. Partnership second year. Write: MINNESOTA MEDICINE — 315; 496 Lowry Medical Arts Building, St. Paul 55102.

The man who is a pessimist before forty-eight knows too much; the man who is an optimist after forty-eight knows too little. — Mark Twain

Much smoking kills live men and cures dead swine. — George Prentice

Why not Miltown®?

There are few "nots" in Miltown® therapy

- Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.
- The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.

Indications: 'Miltown' (meprobamate) is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, 'Miltown' fosters normal sleep through both its anti-anxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of pre-existing symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: In two strengths: 400 mg. scored tablets and 200 mg. coated tablets.

Before prescribing, consult package circular.

Hygroton®
brand of chlorthalidone

the long-acting diuretic

Indications: Many types of edema involving retention of salt and water.
Contraindications: Hypersensitivity and most cases of severe renal or hepatic disease.
Precautions: Reduce dosage of concomitant antihypertensive agents by at least one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take special care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.
Side Effects: Agranulocytosis, constipation, dizziness, dysuria, headache, hyperglycemia, hyperuricemia, impotence, leukopenia, muscle cramps, nausea, postural hypotension, purpura, thrombocytopenia, transient myopia, urticaria, vomiting and weakness.
Average Dosage: One tablet (100 mg.) daily with breakfast.
Availability: Tablets of 100 mg. in bottles of 100 and 1000.
For full details, see the complete prescribing information.

good riddance

Hygroton, brand of chlorthalidone, gets rid of edema efficiently. Your edematous patients will generally need far fewer tablets than with most diuretics. And they'll generally save more on prescription costs. One tablet a day is a popular dosage. So is one tablet every other day. You may even find half a tablet three times a week does the job. No other diuretic works as long. And none has as much natruretic activity per tablet.* For good riddance of edema with the least number of tablets, prescribe Hygroton, brand of chlorthalidone.

DEXTROSTIX®...for quantitative blood-glucose estimations

BRAND REAGENT STRIPS

With DEXTROSTIX, quantitative blood-glucose estimations are possible in one minute. Utilizing one drop of either capillary or venous blood, testing can be completed while the patient is still in the office. Thus with DEXTROSTIX you have a diagnostic aid of great versatility. A clinically significant range of readings is available with easy-to-use DEXTROSTIX, making this new test invaluable in physical examinations, routine checkups of your diabetic patients, and in emergencies.

78964

DEXTROSTIX provides fast, simple screening for diabetes in its earliest stages. Recent investigation has indicated that "...there is a large group of patients with mild, asymptomatic, diabetes mellitus who remain undetected unless blood tests are employed routinely."*

Available: No. 2888 Bottle of 25 Reagent Strips (color chart provided on bottle label).

**for
The Age of
Anxiety**

In prescribing: Dosage—Adults: Mild to moderate anxiety and tension, 5 or 10 mg t.i.d. or q.i.d.; severe states, 20 or 25 mg t.i.d. or q.i.d. Geriatric patients: 5 mg b.i.d. to q.i.d. *Cautions*—Occasional side effects, often dose-related, are drowsiness, ataxia, minor skin rashes, menstrual irregularities, nausea and constipation. Paradoxical reactions may occasionally occur in psychiatric patients. Individual maintenance dosages should be determined. Advise patients against possibly hazardous procedures until maintenance dosage is established. Though compatible with most drugs, use care in combining with other psychotropics, particularly MAO inhibitors or phenothiazines; warn patients of possible combined effects with alcohol. Observe usual precautions in impaired renal or hepatic function, and in long-term treatment. *Supplied*—Capsules, 5 mg, 10 mg and 25 mg, bottles of 50 and 500.

THE POWER
OF NEGATIVE
THINKING

No doubt you have attached diagnostic importance to negative findings for years. When you apply your stethoscope, all is usually normal. When you test for reflexes you generally find them normal, too. In your routine urine checks with dip-and-read **HEMA-COMBISTIX**T.M. Reagent Strips, you generally discover that urinary blood, protein, and glucose are absent, and pH normal. But when you discover an abnormal finding you may, within 60 seconds, have detected pathology well in advance of the appearance of related symptoms. ☐ Ames Company, Inc., Elkhart, Indiana. 68964

The Somatic Mask: chest pain—heart disease or psychic tension?

Precordial pain as well as tachycardia, palpitation, breathlessness and faintness or arrhythmias are classic signs of cardiac disease. In many cases, however, they may represent a "somatic mask"—a psychophysiological equivalent of psychic tension.

Valium (diazepam) reduces the patient's disturbing psychic tension and helps improve such related symptoms as sadness and feelings of hopelessness, fatigue, insomnia, crying spells and nervousness.

In prescribing: Dosage—Adults: Mild to moderate psychoneurotic reactions, 2 to 5 mg b.i.d. or t.i.d.; severe psychoneurotic reactions, 5 to 10 mg t.i.d. or q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hrs, then 5 mg t.i.d. or q.i.d. as needed; muscle spasm with cerebral palsy or athetosis, 2 o 10 mg t.i.d. or q.i.d. Geriatric patients: 1 or 2 mg/day ini-lly, increase gradually as needed.

ntraindications: Infants, patients with history of convulsive sorders or glaucoma.

arning: Not of value in the treatment of psychotic patients, nd should not be employed in lieu of appropriate treatment.

Precautions: Limit dosage to smallest effective amount in elderly patients (not more than 1 mg, one or two times daily) to preclude ataxia or oversedation. Advise patients against possibly hazardous procedures until correct maintenance dosage is established; driving during therapy not recommended. In general, concurrent use with other psychotropic agents is not recommended. Warn patients of possible combined effects with alcohol. Safe use in pregnancy not established. Observe usual precautions in impaired renal or hepatic function and in patients who may be suicidal; periodic blood counts and liver function tests advisable in long-term use. Cease therapy gradually.

Side Effects: Side effects (usually dose-related) are fatigue, drowsiness and ataxia. Also reported: mild nausea, dizziness, blurred vision, diplopia, headache, incontinence, slurred speech, tremor and skin rash; paradoxical reactions (excitement, depression, stimulation, sleep disturbances and hallucinations) and changes in EEG patterns. Abrupt cessation after prolonged overdosage may produce withdrawal symptoms similar to those seen with barbiturates, meprobamate and chlordiazepoxide HCl.

Supplied: Tablets, 2 mg and 5 mg; bottles of 50 and 500.

Benadryl®

(diphenhydramine hydrochloride)

PARKE-DAVIS

To Combat Symptoms of Weed-Pollen Allergy

This time-tested agent provides two actions that effectively combat symptoms of seasonal allergy: *Antihistaminic*—relieves sneezing, nasal congestion, itching, and lacrimation. *Antispasmodic*—relieves bronchial and gastrointestinal spasm. **Precautions:** Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this product. Hypnotics, sedatives, or tranquilizers, if used with BENADRYL, should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENADRYL. **Side Effects:** Side reactions, commonly associated with antihistaminic therapy and generally mild, may affect the nervous, gastrointestinal, and cardiovascular systems. Most frequent reactions are drowsiness, dizziness, dryness of the mouth, nausea, and nervousness. BENADRYL is available in Kapseals® of 50 mg. and Capsules of 25 mg. diphenhydramine hydrochloride. The pink capsule with the white band is a trademark of Parke, Davis & Company.

BSP® DISPOSABLE UNIT

H.W.&D. BRAND OF SULFOBROMOPHTHALEIN SODIUM INJECTION, U.S.P.

(50 mg. per ml.)

Bromsulphalein (BSP), one of the most sensitive diagnostic agents for evaluating liver function, is now available in a new Disposable Unit. Each "unit" contains: A sterile BSP syringe calibrated in milliliters and pounds (utilizing the 5 mg./kg. BSP dosage schedule), a sterile disposable needle, alcohol swab and a 7.5 or 10 ml. size ampule of BSP.

The precalibrated dosage schedule imprinted on the syringe barrel makes weight calculations unnecessary—saving time and assuring proper administration of the dye, regardless of patient-weight.

Literature on indications and dosage available on request.

The NEW BSP DISPOSABLE UNIT is supplied in 7.5 and 10 ml. sizes in boxes of 10's and 25's.

NTZ Nasal Spray relieves hay fever symptoms on contact

Fast symptomatic relief from seasonal hay fever comes in the convenient NTz Nasal Spray bottle. Two sprays quickly relieve itching and decongest the nasal membranes on contact. The first spray of NTz shrinks the turbinates, helps restore normal nasal ventilation and breathing. After a few minutes a second spray enhances sinus ventilation and drainage.

NTz Nasal Spray reduces excessive rhinorrhea without unpleasant dryness. It is well tolerated by delicate respiratory tissues. NTz also provides relief in head colds, perennial rhinitis and sinusitis.

NTz's carefully balanced formula relieves three ways: with a decongestant, a topical antihistamine, and an antiseptic wetting agent.

Neo-Synephrine® HCl 0.5%, a decongestant of unexcelled efficacy to shrink nasal membranes.

Thenfadil® HCl 0.1%, a topical antihistamine to help relieve itching.

Zephiran® Cl 1:5000, an antiseptic wetting agent to promote the rapid spread of components to less accessible nasal areas.

NTz is supplied in leakproof, pocket-size, spray bottles of 20 ml. and in bottles of 30 ml. with dropper.

Winthrop Laboratories, New York, N. Y. 10016

NTZ, Neo-Synephrine (brand of phenylephrine), Thenfadil (brand of thenyldiamine), and Zephiran (brand of benzalkonium, as chloride, refined), trademarks reg. U.S. Pat. Off.

GENERAL INFORMATION

Authors

Manuscripts for consideration in Minnesota Medicine should be addressed to Office of Publication, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102. Papers should be typed double spaced on white paper with a wide margin. The first page should list the title, the name of the author (or authors), degree, and any institutional or other credits. Pages should be numbered consecutively. Tables should be typed and numbered and should have a brief descriptive caption.

Bibliographical references should be limited to twelve and should be typed in conformity to the method used by the Index Medicus. They should be numbered consecutively in the order in which they first appear in the text. Book references should give the name of the author, title, edition number, publisher, and the year.

Illustrations (photographs, tables, and graphs) should be submitted on separate sheets of paper and not combined in the text. Instructions for combining photographs are acceptable.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

President's Letter

There is much written and said about the image of the physician in today's society. In an earlier day he was better educated than most of his fellow citizens and was regarded as always available to anyone in distress. Today a greater portion of any community is well educated and the physician may have become less available as he has become more specialized. Polls of opinion, however, show that our profession still maintains a position high in public esteem, although the individual physician may be more highly regarded than the organizations to which he belongs. Many factors such as specialization, group practice, the increased complexity of diagnostic procedures, third party prepayment and insurance plans, and government medicine serve to depreciate or obscure the role of the individual physician. Such trends become more evident as the size of the community increases.

There are two factors in our public relations which are important in maintaining a high level of esteem. The first is ready availability of satisfactory medical care. This can be accomplished by a composite of individual and group action. No propaganda of any type can be as impressive to the patient as the kindly and careful attention of his physician. Patients probably do not expect that each physician will always be at beck and call, but they should know how to obtain satisfactory service outside of regular hours. The unprecedented number of patients appearing at hospital emergency rooms for ordinary care reflects this need. Physicians and the local medical society have an obligation to provide a service organized for good care and made known to the public.

Another facet of good public relations is community service. Working with fellow citizens provides an opportunity to exchange ideas and ideals. I have found that people are more willing to discuss medicine's problems with me when I have served with them in church, chamber of commerce, or United Fund activities. Party workers in either political party will listen more intently to the physician if he participates in the discussion of all issues, not just those of medical interest. Dr. Walter Judd has pointed out that the medical profession is seldom heard from except when its own problems are involved. We should be widely informed and active in community affairs. Most physicians are too busy to participate in many activities but each of us should find time to contribute to a worthwhile endeavor which brings contact with other responsible citizens. There are some who still live and practice in an ivory tower believing that medical service is enough. A community, large or small, thrives on a balanced leadership from all its segments, and medicine should not be unrepresented lest it be misrepresented.

WITH HAND WEIGHT OFF
ADD 20 GRAMS TO READING

Keeping an eye on the scales may be an avocation with some people, but it is a full-time occupation for Lilly employees who determine the weight of filled tubes of medication. First, a random sampling of empty tubes is taken, and the average weight is calculated. Then, the amount of ingredient is added to this figure to determine the standard fill. As the machine fills the tubes, a sample—about one out of every four hundred—is weighed and checked against the standard. The weights are plotted on a graph. A variation of three consecutive points in either direction indicates a trend away from the standard, and the machine is adjusted. Tolerances are kept to less than 5 percent. An extra step . . . but consistent with the meticulous program at Eli Lilly and Company to assure the highest quality in our finished products.

Composite Grafts

For Repair of Nasal Losses*

LYLE V. KRAGH, M.D.
Minneapolis, Minnesota

OCCASIONALLY PERSONS sustain losses of ala, tip or columella of the nose that are difficult to repair. Many of these losses are the result of avulsion-type auto or machine accidents or of dog bites. Also, the person whose face is severely burned may lose full thickness substance of the lower part of the nose. Carcinomas of the lower nasal skin may be deeply invasive and require full thickness removal for their eradication, leaving a similar type defect. It must be emphasized that the nasal losses under discussion here are through-and-through full thickness losses, not just of the surface skin.

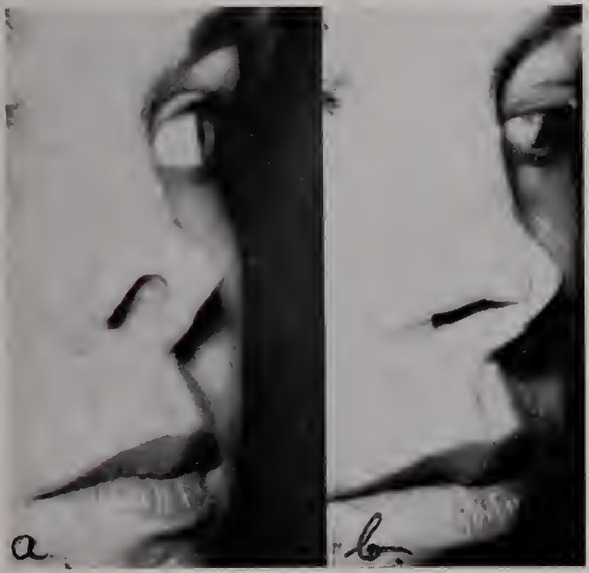

Fig. 1 — *(a)* Traumatic loss of portion of ala and tip of nose. *(b)* Repair of defect of ala and tip utilizing two composite ear lobe grafts. The ear lobe grafts were transplanted to the nose in two operations about five months apart. The patient still requires a small amount of revision of areas about the tip.

Some nasal tip and alar defects can be repaired by a local rotation flap of skin or a pedicle of skin brought to the nose from a more distant part of the body.

The Composite Graft

The method to be presented here is the use of a composite graft (usually taken from the ear) to restore losses about the tip and lower border of the nose.

The composite graft is a free graft which includes not only skin but additional underlying tissue. For repair of defects about the thin rim of the nose, the donor site for these grafts is usually the patient's own ear. Thus these grafts contain skin, subcutaneous tissue and cartilage, if from the helix of the ear; and skin, subcutaneous tissue and fat, if from the ear lobe. From the rim of the helix and from the ear lobe, skin will be present on both surfaces of the graft. These autografts are somewhat similar to the surgically replaced amputated finger tip or the freely transplanted nipple in the reduction mammoplasty.

---

*Presented at the Minneapolis Academy of Medicine, December 21, 1964 .

For the most part, these grafts are used about the columella, tip and ala of the nose. They are thick, with sufficient rigidity and sharpness to restore the contour of the nostril border or to replace most of the entire nostril.

Though these grafts were used successfully on a few occasions in the early part of this century, the large experience in their use came from the military plastic surgical centers during World War II.[3] Brown and Cannon and associates[1,2] at Valley Forge Army Hospital reported on a large number of repairs using composite skin-cartilage grafts from the ear. Dupertius,[6] then at the Philadelphia Naval Hospital, reported on successful similar type repairs using grafts from the ear lobe.

Advantages

The appearance of the healed graft is often quite satisfactory and may be superior to anything that can be obtained with a local pedicle flap of skin. The ear grafts usually match the nose skin well and are not very conspicuous. Also, grafts from the helix or lobe have a very satisfactory shape for use about the ala or nostrils.

Disadvantages

The major disadvantage in the use of free composite grafts is the size limitation for successful take. This thick graft of several tissues must be nourished from the recipient vascular bed, and generally no portion of the graft should be more than one centimeter from the nearest blood supply. In repairing losses about the nostril rim, the graft can be several centimeters long, but the maximum thickness should be about one centimeter or less. Occasionally a large alar defect can be repaired in two or more stages. At the first operation, a large portion of the loss can be replaced and still stay within the safe limits of graft width of about one centimeter. Then at the second operation, several months later, additional grafts can be inserted to correct the remaining defect.

The Technique

The grafts should be transplanted on clean surgical wounds that are free of scar. Hinge-type flaps of nasal skin about the periphery of the defect may be developed which will increase the raw surface and thus increase the size of the vascular bed to nourish the graft. An exact pattern of the tissue requirements is determined by using metal foil. This pattern is then transferred to the ear and a donor site selected to produce a satisfactory graft and to result in as little ear deformity as possible. The graft is then marked on the ear and very carefully cut out. It is handled only with the moistened gloved fingers, avoiding crushing instruments, and is transferred to the nose and sutured in place with very fine sutures. Atraumatic technique in the cutting, transferring and suturing of these grafts is very important for a successful take.

Immediately after the graft is sutured in place, it is pale white, indicating no circulation of red blood cells at that early stage. However, by twenty four hours, and often as early as six to twelve hours, a pinkish tinge may be present in the graft.[7] In most cases, by the second day blood has definitely entered the graft and a good blood supply is established by the fourth day, confirmed by blanching on pressure and return of the pink color on releasing the pressure. The quantity of tissue that must become vascularized and receive nourishment in these thick composite grafts is many times more than in a thin split-thickness or full thickness graft of skin alone.

In most instances of fresh traumatic loss of a portion of the nose, such as a dog-bite avulsion, it is preferable to obtain healing by primary suture or application of a split-skin graft to the area that cannot be closed by suture. Several months later, with a surgically clean wound and under optimum conditions the reconstruction can be carried out with a better chance of success. Immediate repair of alar losses from removal of an epithelioma can often be accomplished satisfactorily with an immediate composite graft.

In these grafts a large block of tissue must receive nourishment from the recipient bed. Increasing the size of the bed by use of a hinge-flap or a tongue-in-groove type graft is helpful.[5] Also, reducing the metabolism of the composite graft by cooling (ice over the dressing or exposure of the graft to air) appears to enhance the chance of successful take.[4]

Ideally, all of the scar tissue should be excised from the base. However, in severe nasal injuries, complete removal of all this scar is impossible. Also the area to be grafted may be an old area of radiodermatitis, a less than optimum situation. The success of the grafts will depend upon the size of block transplanted, the suitability of the recipient's bed and the careful technique with which the graft is handled and sutured in place. With favorable circumstances a success rate of 80-90 percent should be obtained.

Summary

The composite graft is especially useful for correcting defects of the nasal ala, tip and columella that are often not satisfactorily corrected by other methods such as pedicle skin flaps. Relatively large pieces of skin plus cartilage or fat can be transplanted to the nose and will be vascularized rapidly if carefully handled and sutured in place on a surgically clean scar-free bed. With precise technique, a satisfactory acceptance of the grafts should be expected in at least 80 percent of cases. When the grafts are obtained from the ear, the shape and color usually match the nose well and the final appearance is generally satisfactory.

URETERAL SYNDROME OF LEDUC

LeDuc has indicated that the ureteral syndrome may stimulate acute appendicitis, differing in the fact that the point of maximal tenderness is over the ureteral point instead of over McBurney's point and pain may begin on the right side rather than in the epigastrium, as in appendicitis. The examination indicates there is no rigidity, muscle spasm or rebound tenderness as there is in acute appendicitis.

The location of typical ureteral pain in the male is in either one or both loin or groin along the course of the ureter, and pain may be referred to the external genitalia or into the inner aspect of the thigh. Associated with this there will be urgency of urination as the bladder fills.

Drive Safely

Thalamotomy

JIM L. STORY, M.D.
MANFRED J. MEIER, M.D.
SHELLEY N. CHOU, M.D.
LYLE A. FRENCH, M.D.
Minneapolis, Minnesota

THE SYMPTOMS of Parkinsonism can be at least temporarily and partially relieved by stereotaxic neurosurgical procedures. This was originally shown by Spiegel and Wycis.[3,4,6] Subsequent experiences have validated this concept and there are now many patients readily available to verify this. That the procedure is invaluable in the control of the disabling symptoms is beyond question. All patients are not helped by the procedure, however.

The purpose of this report is to present our experiences with lesions produced by the stereotaxic technique in the subthalamic region to control symptoms of this disorder. Our prime effort has been to determine which patients will respond most favorably to surgical treatment. It is true that there is a modicum of difficulty in proper placement of the lesion, but perhaps even more important is the proper selection of patients. These two factors are of equal importance.

Method and Material

A modification of the stereotaxic method of Spiegel and Wycis[4] is utilized to locate the internal reference points, the anterior and posterior commissures, and to place the lesion in the subthalamic region. Localization of the optimal target point is determined radiographically and by physiological method, the latter consisting of a high frequency stimulus applied to the target area with the patient in the awakened state. The stimulus is delivered through a 1.1 mm. diameter concentric electrode which has been passed through a burr hole into the target area. The end point for lesion placement is blocking of tremor in the contralateral extremities for the duration of the stimulus with the least possible amount of current. A 50 to 100-cycle per second, 2 msec. square wave pulse of 0.1 to 0.5 mA or 1 to 5 volts usually blocks the tremor when the optimal target point has been achieved. The stimulating electrode is then replaced by the Bertrand[1] leukotome and the lesion produced. Immediate arrest of tremor and rigidity follows.

---

*Inaugural thesis presented to Minneapolis Academy of Medicine, November 16, 1964.

• in • the • Treatment • of • Parkinsonism*

TABLE 1
Results of Thalamotomy in 50 Patients with Parkinsonism

Results	Number of Patients	Percentage of Total	
Good	16	32%	56%
Fair	12	24%	
Poor	22	44%	

Lesions in the subthalamic region have been placed in fifty patients. The experimental studies of Strassburger and French[5] have shown this region to be particularly effective in the control of tremor and rigidity. Postsurgical follow-up of forty-eight of the fifty patients ranges from two to 33 months, with an average of 16 months. Preoperative manifestations of the disease in many of these patients have included, in addition to the typical tremor and rigidity, marked akinesia (poverty of movement), masked facies, and vegetative signs such as flushing, seborrhea and excessive sweating.

The patients have been divided, according to results, into good, fair, and poor groups. The various groups are defined as follows:

Good: a) relief of tremor and/or rigidity
b) over-all functional improvement

Fair: a) some recurrence of tremor or rigidity but less than preoperatively
b) functional improvement subjectively and objectively

Poor: a) no improvement
b) worsened by the procedure
c) temporarily improved but over-all poor because of progression of the disease

Results and Discussion

There were 16 or 32% good, 12 or 22% fair, and 22 or 44% poor results. Combining good and fair, there were 28 or 56% improved (Table 1).

There were no deaths in this group of fifty patients. There was one postsurgical hemiplegia, and four patients developed a mild hemiparesis. Two demonstrated an increase in tremor, and five were considered to have worsened by the procedure.

A review of pertinent clinical variables suggests that operative results are a function of symptom duration and the amount of preoperative akinesia.

Table 2 shows distribution data and significance tests for differences between the groups in duration of symptoms according to number of years. It can be seen that the difference of 10.6 years in duration between the good and poor outcome groups yields a t ratio of 4.09, which is significant at the .001 level of confidence. That is, a difference of that magnitude would not be expected to arise more than once in 1000 comparisons on a chance basis. Similarly, .001 level differences arise when the combined fair and poor groups are compared with the good group and when the combined good and fair groups are compared with the poor group. Thus, a positive relationship between outcome and symptom duration is strongly suggested.

The comparisons between outcome classification and preoperative ratings of akinesia can be seen in Table 3, where the amount of akinesia was rated along a nine point scale: 0, 1, 1+, 2, 2+, 3, 3+, 4, 4+. These ratings were broken down for purposes of analysis into three sectors: Absent (0), Mild (0+ through 1+), Severe (2 or more). The observed and expected frequencies for each outcome group on each sector are located in the nine-fold Chi-square matrix of Table 3. All of the good group exhibited mild or no akinesia, while the poor group was divided, with a preponderance of severe akinesias but none with absence of akinesia. The Chi-square of 19.56 yields a probability of one in 1000 for obtaining the observed frequencies on a chance basis. Similarly, combining the fair and poor groups or the good and fair groups for comparison with the remaining group shows significant deviation from chance expectancy as inferred from the obtained Chi-square values. Thus, the more akinesia* judged to be present preoperatively, the more likely is a poorer outcome to follow thalamotomy in this series of patients.

TABLE 3
Comparisons Between Clinically Estimated Outcomes of Thalamotomy as a Function of Preoperative Ratings of Akinesia

		Outcome		
		Good	Fair	Poor

Even though there was no definite history of encephalitis in all patients who had suffered from Parkinsonism for many years, it is our impression that these patients most likely were postencephalitic Parkinsonians. In a number of instances, a definite history was obtained of encephalitis, followed soon thereafter by tremor. One patient related the onset of tremor to encephalitis following a smallpox vaccination. It is our impression that many inflammatory or toxic diseases of the nervous system, often subclinical, may be followed in time by the Parkinson syndrome. It is emphasized that this is a true syndrome, a composite of symptoms, not a

*See Test Your Word Score Page 901.

specific disease entity.

In general from the data presented, the best results are obtained in the following patients: 1) those with illness of long duration, 2) those who are physiologically young, 3) those with good mental status, a good facial expression and lack of vegetative findings and 4) those with minimal akinesia.

Bilateral tremor or rigidity does not preclude good results provided conditions (1) through (4) are satisfied.

Though it is our feeling that the above criteria for selection of patients are generally true, it has been gratifying and surprising at times to obtain considerable improvement in patients who would have been considered fair or poor candidates for surgical treatment. This improvement is usually transient but, even so, most patients believe it is worth while.

Summary

Fifty patients suffering from Parkinsonism have undergone subthalamotomy with 32% good and 22% fair results. Over-all 56% have been improved by the procedure.

The best results are obtained in those patients with illness of long duration, those who are physiologically young, those with good mental status, good facial expression, lack of vegetative findings, and those with minimal akinesia.

Careful selection of patients should yield improved surgical results.

Resourcefulness of Medicine

Medicine appropriates everything from every source that can be of the slightest use to anybody who is ailing in any way, or likely to be ailing from any cause. It learned from a monk how to use antimony, from a Jesuit how to cure ague, from a friar how to cut for stone, from a soldier how to treat gout, from a sailor how to keep off scurvy, from a postmaster how to sound the Eustachian tube, from a dairy maid how to prevent smallpox, and from an old market woman how to catch the itch insect. It borrowed acupuncture and the moxa from the Japanese heathen, and was taught the use of lobelia by the American savage.—Oliver Wendell Holmes

---

More than one woman has been rendered unhappy for the rest of her life, has been lost and dishonored by a man whom she has ceased to love, because he took off his coat awkwardly, trimmed one of his nails crookedly, put on a stocking wrong-side-out and was clumsy with a button. — Quoted by Balzac

---

Ignorance is the night of the mind, but a night without moon or star. — Confucius

*The Place of Jesus in the History of Medicine**

Part II

Christianity entered the world as a religion of redemption. The starting point for the man who would espouse this religion was not an awareness of his worth or power, but of his failure, sin, and suffering. The basic preaching of Jesus and his apostles was "repent and believe the gospel." (Mk. 1:15). Repentance put in its simplest terms is that self-awareness in which men admit their sin and their impotence in the face of it; to believe in the gospel meant to have faith in God's healing or redemptive power. This new religion was grounded not in the glorification of human greatness but in the free and frank acceptance of human suffering, illness, and sin. Jesus was called the Savior, in Greek *Soter* or "healer." His redemptive work is repeatedly described by analogy with the work of a physician in curing the ill. Justin, a church father of the second century, wrote: "Like some excellent physician, in order to cure the sick, Jesus examines what is repulsive, handles sores, and reaps pain himself from the sufferings of others. . ."

This new attitude of acceptance and concern for the ill was rooted in the ministry of Jesus himself. Jesus came healing. He did not explain that sickness is health; he called it by its proper name. He also denied that suffering was the will of God, or a direct and personal punishment for sin. (Lk. 13:1-5). Instead, it was the work of Satan and as such to be resisted and eliminated. (Lk. 13: 16). Jesus brooked no interference in his ministry of healing. The work of healing took precedence over even the most sacred religious traditions, such as Sabbath observance. (Mt. 12:9ff).

Jesus brought into western civilization a new attitude of concern and acceptance for the care and treatment of the ill which has found expression in the growth of modern medical care. Without this basic humanitarian concern, not only for man in his greatness and goodness, but also in his frailty, suffering and illness, the powers of science would never have been harnessed to the cure of disease. The future course of scientific medicine will be marked by growing success as long as its practitioners work in the conviction that their endeavor must be dedicated to achieving for man that wholeness which God intended man to have.

Australopithecus**

The specialized human foot makes possible a balanced, erect posture and rapid movement without recourse to an all-fours position. No ape or monkey has the capacity. He may stand erect momentarily, or stagger along for a distance, but his hands are never freed permanently for chores other than locomotion. Similarly, the special development of that mass of muscle centered in the human buttocks makes possible agility and all the turning and twisting and throwing and balance of the human body in an erect position. As the brain co-ordinates our nervous activity, so the buttocks co-ordinate our muscular activity. No ape boasts such a muscular monument to compare with ours; and it is a failure more fundamental than his lack of an enlarged brain.

Regard yourself. Take pride in your hat-size if you will, but it was the specialization of feet and buttocks that made all else possible, and that truly distinguishes you from all other primates, living and dead, with the single exception of australopithecus.—African Genesis—Robert Ardrey

*Blood Group Antibodies as They Affect Transfusion Practices**

DOUGLAS W. HUESTIS, M.D.**
Chicago, Illinois

Caution is the ever present "key word" in blood transfusion practices.

IN OPERATING a blood transfusion service we are always dealing with an interplay of antigens and antibodies. From an increasing knowledge of the vast numbers of blood group systems and antigens, we can safely say that every time a person is transfused he is exposed to some antigenic factor or factors which his body will identify as foreign, and to which he may build up antibodies.

At any rate, the more transfusions we give, the more important antibody formation becomes, and the more different varieties of antibody formation we shall be able to study. Those who are responsible for a blood transfusion service, therefore, have to learn to live with antibodies, to expect them to turn up, to set up technics to catch them, and be prepared to make a rapid evaluation of the problem in any given case. Can it be handled with the locally available facilities? Or will outside help be needed?

Acknowledging first that unexpected blood group antibodies do turn up now and then, it is worthwhile to start thinking first of all about how much of a problem this is. In other words, is it really anything for the average transfusion service to be much concerned about?

Irregular antibodies occur a great deal more often than most people realize. At our Center in Chicago we investigated 280 immunohematologic problems in 1963. Of these, almost half came from our own hospital, which has 425 beds and where about 3900 transfusions were given in 1963. This does seem rather a lot of antibodies, even though it includes such things as cold agglutinins when they interfere with a crossmatch. It does not, however, include Rh antibodies as usually determined in prenatal testing. In a study reported by Grove-Rasmussen (Transfusion, May-June, 1964) nearly 40,000 antibodies were detected in 20 reference laboratories out of approximately 2,000,000 specimens either referred to them or passing through their hands, including cases of hemolytic disease of the newborn. This makes an overall occurrence figure in this group of somewhere between 1 and 2%. It is my impression that the vast numbers of antibodies never come to light. They lurk on in their possessors and when the occasion for another transfusion or a blood donation rolls around they may or may not be detected.

Strong Antibodies — High Incidence Factor

It is tempting to say that the really important antibodies from the clinical point of view will be obvious and should require no comment. Unfortunately, this is by no means true as the following case will illustrate.

Case Reports

Case No. 1

Some time ago a 34-year-old woman at another hospital received a unit of blood which had been crossmatched by the night technician and was considered compatible. No adverse effects were reported to the blood bank until a few days later, at which time the blood bank was notified that complete renal shutdown had occurred. Blood specimens from the patient (post-transfusion) and from the donor whose blood had been administered were sent to us. Both were group O, Rh-positive. However, there was major incompatibility between patient and donor, with hemolysis of the donor cells. The patient's serum also reacted with all other panel cells except the patient's own cells. We are thus dealing with a hemolytic antibody to a high-incidence blood factor. Further investigation disclosed that Vel-negative cells were not affected, that all reacting cells were Vel-positive, and that the patient was apparently Vel-negative. Vel antigen can at times be quite difficult to detect, especially in old blood samples. During the investigation, the patient died.

Unfortunately, a pre-transfusion blood sample of the patient had not been saved, so we were not exactly sure of the way the crossmatch may have reacted. However, we surmise that the presence of hemolysis may have been overlooked.

In this case, a clearly demonstrable antibody must have been present. Apparently, for one reason or another, the night technician failed to note the incompatibility. It may well be that the largest single factor involved here was a certain degree of "automatism": the night technician selected blood of the same ABO and Rh type as the patient, set up the crossmatch and expecting it to be compatible failed to note the hemolysis. Many other less tangible factors may have been involved.

Another case will add emphasis.

Case No. 2

In Paris, a young woman bled from an ectopic pregnancy and was given a single unit of uncrossmatched blood as treatment for shock. It was her misfortune to be phenotype p (Tj^a-negative) and of course the unit she received was P_1 or P_2 (thus Tj^a-positive). As with most people of this blood type, she had strong anti-$P+P_1$ antibodies, and she went into renal failure. Blood of type p was needed for dialysis. She was able to get one unit from a sister in France, one from the only available donor in England, one from us in Chicago, and one from Australia. Thanks to this strenuous intercontinental effort she survived and is well today. Here we have one of the known hazards of the use of uncrossmatched blood.

In both of these cases, we were dealing with strong antibodies to high-incidence factors; hence both are statistical rarities. Being a statistical rarity, however, is scant comfort to the person who gets incompatible blood. The moral in each of these cases is obvious. In the first, alertness on the part of the person responsible for a crossmatch must be unremitting, and his attention must always be actively focused on the task at hand. In the second case the hazards inherent in the use of uncrossmatched blood must not be forgotten.

Weak Antibodies

Having concluded that the potent irregular antibodies are important, we may now question whether the weaker ones really matter. This is a much more difficult matter to decide, because whether an antibody appears to be strong or weak or even undetectable may depend on the method used to detect it.

Case No. 3

Quite a few years ago, for example, in another city I had a surgical patient with anemia due to chronic infection. This patient had had many transfusions without a very good response. Looking into the patient's chart later, we noted clinical comments that there was a very poor response to transfusions, even commented on by a consultant hematologist. In the nurse's notes were remarks of chills and headaches after some of the transfusions. These findings had unfortunately not been communicated to the Blood Bank. The crossmatches were compatible in saline and high protein media. Just at that time I decided to improve our crossmatch routine by adding an antiglobulin crossmatch in multiple transfusion cases. A beautiful anti-Fy^a (Duffy) was promptly detected in the patient's serum. Administration of Fy^a-negative blood resulted in prompt improvement, no more shaking chills were experienced, and the consultant hematologist was now satisfied with the clinical response to transfusions.

In a case like this, the clinical transfusion reactions were relatively mild, but the patient received little or no benefit from most of his transfusions. This in turn resulted in unduly prolonged hospitalization, unnecessary additional clinical consultations, considerable worry to the patient, and pure wastage of valuable blood, all of which are both costly and distressing.

The important thing in dealing with these contingencies is to adopt a positive outlook instead of the negative one so frequently expressed. Even the weakest, barely detectable antibody in the patient may prevent this aim from being achieved if blood containing the particular antigen is given: for one thing it may promptly convert the weak antibody to a stronger one, as undoubtedly happened in the Duffy case above. Many cases have been seen and reported in which transfused blood had had a very short survival in the recipient despite the lack of any obvious or severe clinical reaction.

In short, we should try to eliminate from our thinking and from that of our clinical colleagues the idea that such and such a procedure is acceptable because we can "get away with it." If I seem to belabor this point a little, I am not apologizing for it. I do so because I think it is extremely important.

Now let us consider a few particular types of antibodies and see what practical lessons can be derived from them. I will omit technical details and concentrate mainly on the general principles involved.

Cold Agglutinins

Cold agglutinins (those reacting with the patient's own cells at 4° C.) often present a real problem to the crossmatching technician and are one of the most frequent reasons for consultation with the Reference Laboratory. In most such cases, if the specimens are kept warm, there should be no difficulty in crossmatching. However, in case of strong cold agglutinins, especially when they have a wide thermal amplitude, it is easier to work with serum from which the cold agglutinin has been absorbed. This is quite easily accomplished by adding the patient's own cells (oxalated are best) to his serum and incubating at refrigerator temperatures. It may be necessary to do this several times, until the serum no longer agglutinates the patient's cells at cold temperatures. The absorbed serum can then be used for crossmatching and antibody detection tests in the usual way.

I mention antibody detection tests because a cold agglutinin may mask the presence of an irregular cold-active blood group antibody. I recall several cases in which we tested such an absorbed serum and found a strong cold-active anti-P, which had been completely masked by the presence of the nonspecific agglutinin. If we had not detected and identified the anti-P, it could have caused further delay by causing crossmatch incompatibilities, which might even have been disregarded as due to some remnants of nonspecific activity, especially if tested with cells having a weak P antigen.

Autoimmune Hemolytic Anemia

In cases of autoimmune hemolytic anemia, blood typing and crossmatching may again be a problem. Here we have had good results with a titration technic on the major crossmatch, using activated papain, and running a control with the patient's own cells. We test blood units as close as possible to the patient's own group and Rh type, and select for transfusions the ones which demonstrate the "least incompatibility" by titration. In our experience such blood has always been tolerated well, providing it is given slowly as packed cells, and preferably not more than a single unit a day. Of course such blood does not usually survive much better than the patient's own cells, which have a shortened life, and often transfusion is best withheld pending the outcome of therapy specifically directed to the autoimmune process. The one thing that should not be done is to choose blindly a group O, Rh-negative unit, hoping it will do. For one thing, some of these patients have an autoantibody of hr″ (e) specificity; hence most Rh-negative blood will survive very poorly indeed.

Hemolysis

Hemolysis is particularly liable to occur in cases of ABO incompatibility, Lewis, P + P_1 (Tj^a), Vel and some others, but not Rh. Technicians must therefore always be on the lookout for hemolysis, not only in crossmatches, but also on reverse typing and antibody screening.

Undetectable Antibody

Now let us consider the antibody that isn't there when you test for it. By this I mean that a person has been sensitized previously and may have had demonstrable antibodies, but no activity can be demonstrated in the serum at the time of testing. This can best be illustrated by two cases, in one of which a reaction occurred.

Case No. 4

This case was published in the AABB Bulletin in November, 1960, and concerns a middle-aged woman who had been transfused only twice previously. At surgery she received eleven units of blood without ill effects. However, one week later she had nausea and vomiting and hemoglobinuria, followed in a couple of days by jaundice and a fall in the hematocrit. By this time it was discovered that she had a positive direct Coombs test and two antibodies: anti-c and anti-Jk^a. It was evident that she had been sensitized previously, but that the antibodies had dropped in titer to such an extent as to be undetectable by either the antibody screening or the good crossmatching technics used by the hospital concerned. When blood containing the offending factors was given, no reaction took place until the antibody titers had again risen, about a week later, at which time destruction of the transfused cells took place. Fifteen months later, the anti-c had again begun to fall in titer and the anti-Jk^a was undetectable, thus again setting the trap.

Case No. 5

A case was referred to us for a crossmatching incompatibility which on investigation appeared to be due to a mixture of anti-c and anti-K. When this information was conveyed to the referring blood bank director, he had in the meantime found in his files a report from our center, dated in 1958, at which time we reported anti-c and anti-Kidd, not Kell. For some reason we were not able to locate our own file on the patient and were inclined to think that "Kidd" must have been a misprint for "Kell." Nevertheless we tried every trick to demonstrate anti-Jk^a (the patient *was* Jk^a-negative) without the slightest success. At this time, when we were about ready to release apparently compatible c-negative K-negative blood and forget about the Jk^a, we found not only the patient's file, but also 280 cc. of her 1958 serum in our deepfreeze! In the 1958 serum we were able to demonstrate anti-c *and* anti-Jk^a, *and* anti-K. Thus after the 1958 transfusions the Jk^a antibody had disappeared. As it turned out the patient got along without transfusion. However, if we had selected c-negative, Kell-negative, Jk^a-*positive* blood for her, which we had been prepared to do, it is reasonable to assume that either an overt delayed reaction would have taken place or, at best, the transfused cells would have begun to be coated and to disappear after a week or so.

Dosage Effect

Before drawing some conclusions from these two cases, I want to mention one other phenomenon which may have important practical implications. Some antibodies exhibit a definite "dosage" effect. By that I mean that they react better with cells which are homozygous for the antigen concerned. A good example of this is often anti-c, which when weak will sometimes react only with homozygous cells and not with heterozygous Rh_1 cells (CcDee). The important implication of this is that a homozygous Rh_1 person with a weak anti-c may be crossmatched with a heterozygous Rh_1 donor and appear compatible. The administration of such blood, however, may cause a reaction or at least would be followed by very poor survival of the transfused cells.

What conclusions can we draw from these two cases and from the observation of the dosing phenomenon?

Selective Screening of Patient and Donor

Crossmatching Alone Not Sufficient

Although it may seem heresy to say so, it is evident that crossmatching is not the only answer to the determination of compatibility between patient and donor. Screening for antibodies with carefully selected screening cells should be carried out on both patient and donor's serum by appropriate technics. Weak antibodies are perhaps more likely to be picked up this way, using fresh specimens, than by crossmatching, by which time the donor blood samples may be getting old.

Identity of Antibody

Second, once an antibody is detected it should be identified, and blood lacking the corresponding antigen should be selected. It is not sufficient in such cases, other than in emergencies, to rely on crossmatching alone to select "compatible" blood, as I hope the foregoing discussion has demonstrated.

Blood Group Warning Card

Third, once antibodies have been demonstrated, either in a donor or a patient, that person should be given a blood group card, stating the presence and specificity of the antibody as a warning in case of future transfusions. Likewise a patient's hospital record should contain a report of the irregular antibody, plus pertinent comments about special crossmatching methods that might be necessary. We have made it a practice to send out an original and a carbon of the Reference Laboratory report, so that the referring blood bank can have one copy and the other may be put on the patient's chart.

Multiple Transfusions

One final case may be of interest and illustrates a few more important points.

Case No. 6

An elderly man with a bleeding peptic ulcer had had many previous transfusions. A specimen of his blood was sent to us because of crossmatch incompatibilities with many donors. We noted an incomplete antibody reacting only with cells in which c and e were derived from the one chromosome, hence anti-f (the patient was A, Rh_1Rh_1). After some transfusions of f-negative blood, two days later a weak reaction with Rh_2 cells was noted and a positive direct Coombs test, and anti-c anti-E were defined. Checking back on previous donor samples, it was possible to show that the Rh_1Rh_2 samples (f negative and compatible when given) were now demonstrably incompatible, and presumably responsible for his coated cells. Further transfusions were all Rh_1Rh_1, hence compatible. Three days later, six out of 20 homozygous Rh_1 donors were incompatible, another positive direct Coombs test was noted, and anti-Fy^b was defined. A few days later, yet another antibody began to appear, reacting with Rh_1Rh_1, Fy^b-negative cells, but could not be definitely identified. On that indefinite note the patient died.

What do we learn from this case about the problems that may be encountered in multiple transfusions over a short period of time?

A patient who has already demonstrated that he can build up one blood group antibody should be regarded with suspicion as a likely candidate for another antibody.

All blood samples from such cases and the pilot tubes from the donor bloods given should be saved for as long as the patient is still being transfused or likely to be transfused. The fourth edition of the Standards for a Blood Transfusion Service (American Association of Blood Banks, 1963) requires that all samples from both patients and donors be kept for at least seven days after transfusion. In this case (Case 6), having the patient's pre-transfusion blood for comparison and especially for the cell-typing was invaluable. Following several transfusions, a person's circulating cells are no longer his own. By the same token, being able to test the pilot samples of blood already given and previously compatible is extremely helpful in identifying antibodies as they develop. We keep all such specimens for a month and it frequently pays off. In the Vel case previously described, if the original patient specimen had been saved, it might have been possible to find out with more certainty why the crossmatch had been reported as compatible.

Most important of all, when a patient is receiving many transfusions over a period of days, a new specimen for screening and crossmatching must be obtained on the day of each transfusion, as new antibodies can develop with surprising rapidity.

Conclusions

I hope that discussion of these cases has served to emphasize the selected points considered. I have wanted to emphasize certain principles of good hemotherapy as I see them, particularly those points which are less generally known and which tend to be troublesome in routine blood banking, and especially from the point of view of keeping the patient with an antibody from getting blood with the offending antigen. I have concentrated on the practical aspects only, but I would not want to finish without reminding you that every blood transfusion and every donor test is an experiment in immunohematology, and that the lessons acquired in such random testing have frequently been invaluable from the scientific point of view.

Finally I want to stress once more the importance of a positive attitude in blood transfusion. Too often people seem to regard it as a triumph that the patient comes through a transfusion alive and without an obvious reaction. That is certainly fine, but blood is living tissue and transfusion is difficult, hazardous and expensive. We owe it to the patient to make sure he gets the greatest possible benefit, and we have a further debt to the donor that his blood be used in the best possible way.

IT'S THE LAW

Failing to Settle within Policy Limits Imposes Liability for Excess

By failing to settle, within the $10,000 policy limit, a personal injury action for damages arising out of an automobile accident, an insurance company became liable for the entire amount of a $35,000 judgment against the policyholder. Offset against the insurer's liability was an amount of $2,000 which the policyholder had offered to contribute toward a settlement within the limits of the policy. The policyholder was required to pay $2,000 toward the judgment, leaving an amount of $33,000 payable by the company.

In holding the insurance company liable, a federal appellate court relied upon a finding of bad faith on the part of the company in failing to settle the case. The court pointed out that the policy contained a provision requiring the company to defend any such action against the policyholder and look after his interests, as well as its own.

Under his public liability policy with the insurance company, he was covered up to the amount of $10,000 which the company paid to the judgment holder after the judgment was affirmed by the Montana Supreme Court. The policyholder died without having made any payment on the judgment. The judgment holder then filed a claim against the policyholder's estate for the excess of the judgment over $10.000 and brought suit on the judgment against the administrator of the estate.

In affirming the judgments, the appellate court concluded that there was bad faith on the part of the insurance company in refusing to settle.

Prior to trial of the case, the injured party offered to settle for $9,000. The insurance company's highest offer was $5,000. The policyholder agreed to contribute an additional $2,000. The insurance company was adamant.

Editor's Note: Although this decision does not involve professional-liability insurance, there does not appear to be any reason why the decision would not be applicable to that kind of liability insurance. — The Citation Vol. 10, No. 1.

Transient Vascular Occlusions

in Acute Strokes[*]

M. G. ETTINGER, M.D.[**]
R. L. RYAN, M.D.[**]
Minneapolis, Minnesota

ATTENTION HAS recently been focused on the role of extracranial occlusive disease in patients with cerebrovascular syndromes. Both angiographic and autopsy studies have confirmed a high incidence of atherosclerotic lesions affecting the carotid and subclavian-vertebral systems, and surgical correction of these defects is being carried out in many areas at the present time. There remains, however, considerable speculation regarding the significance of such lesions in the genesis of the stroke syndrome. Such conflicting data as the repeated demonstration of a complete occlusion in one or more of the extracranial vascular channels unassociated with manifestations of a stroke syndrome on the one hand;[1] a high incidence of encephalomalacia without vascular occlusion on the other; and finally, the continued speculation regarding the role of intracranial vascular disease all tend to suggest that extracranial occlusive disease may be a relatively minor factor in the etiology of the stroke syndrome.

The majority of angiographic studies in stroke cases have not been performed early in the course of this acute illness and do not afford us any reliable information concerning possible transient alterations in intracranial vascular structures.[2,4] The following case reports suggest that temporary occlusion of an intracranial vessel may well be a fleeting phenomenon — persisting long enough to result in tissue destruction (encephalomalacia) — then disappearing so that subsequent angiographic and autopsy studies reveal only encephalomalacia without demonstrable vascular occlusion.

Case Reports

Case No. 1

This 63-year-old female had a past history of arteriosclerotic heart disease and in addition, three years prior to admission, had experienced a transient episode of aphasia. On the morning of admission she suddenly developed aphasia and right-sided weakness. Examination revealed her blood pressure to be 108/60, pulse 84 and irregularly irregular. She demonstrated a marked aphasic disturbance and flaccid right hemiplegia. A lumbar puncture was normal. Between 24 and 30 hours after the onset of her symptoms a left carotid arteriogram was performed which demonstrated nonfilling of the middle cerebral artery. Three days later a repeat left carotid arteriogram, utilizing the same parameters of injection pressure, amount of contrast dye, etc., revealed good filling of the middle cerebral artery (Fig. 1 and 2). Clinically the patient demonstrated only a mild improvement at the time of discharge.

Case No. 2

This 70-year-old female had been discharged from the Medicine Service one day prior to her admission to Neurology following an unsuccessful attempt to convert her atrial fibrillation to a normal rhythm.

---

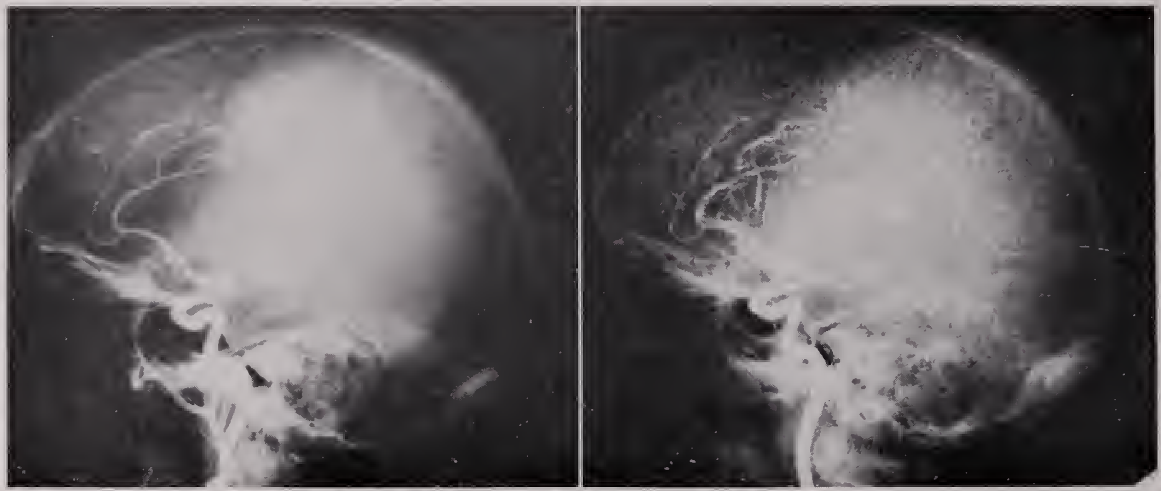
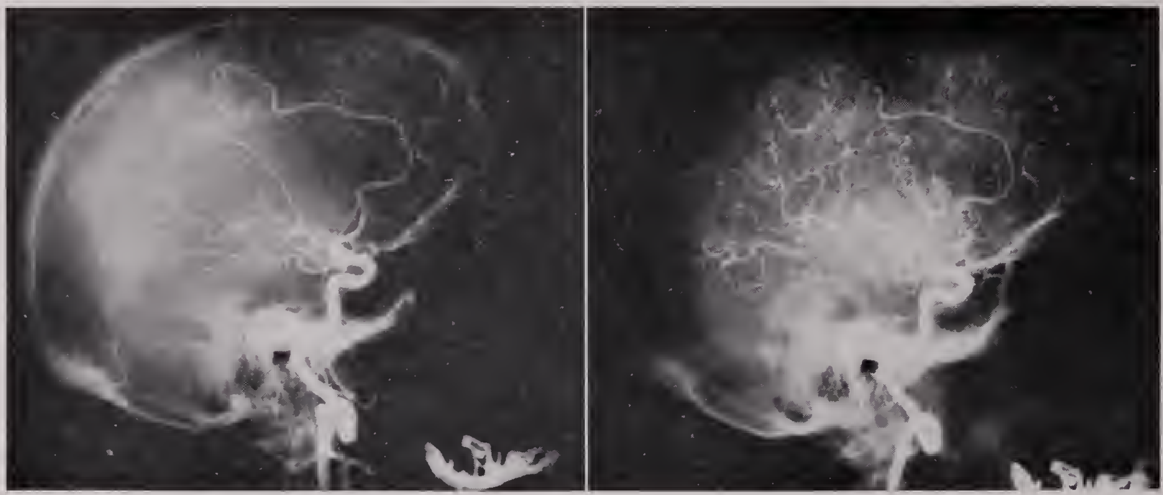
[**] Neurology Service, Hennepin County General Hospital.



Case 1

24 hours after onset

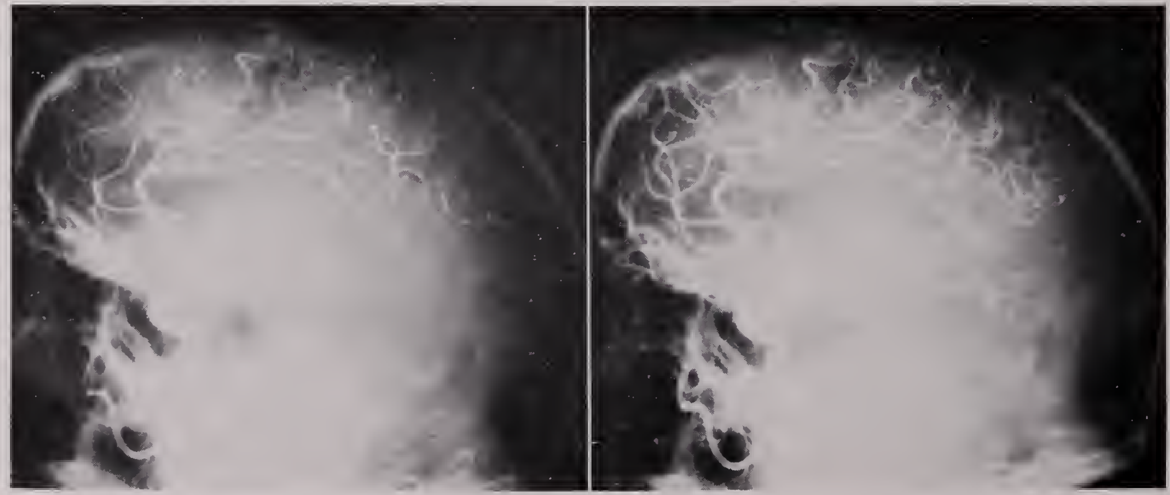
4 days after onset



Case 2

24 hours after onset

4 days after onset



Case 3

14 hours after onset

62 hours after onset

On the day of admission she was found at home, hemiplegic and semicomatose. At the time of initial examination her blood pressure was 160/90, pulse 52 and irregularly irregular. She demonstrated a marked aphasia and right hemiplegia. Her spinal fluid was normal. A left carotid arteriogram performed 24 hours after the onset of symptoms demonstrated occlusion of the sylvian branches of the middle cerebral artery. Three days later a repeat arteriogram revealed filling of the previously occluded segments. Clinically there was little improvement, and the patient was discharged four weeks later with a severe hemiplegia and aphasia (Fig. 3 and 4).

Case No. 3

This 73-year-old male was being followed in the Medicine Clinic for a severe cardiac arrhythmia with a flutter-fibrillation and a variable heart block. On the morning of admission the patient awoke with severe aphasia and right hemiparesis. Blood pressure was 100/60, pulse 72 and markedly irregular. He demonstrated a severe aphasia, right central 7th paresis, mild right-sided weakness, and a conjugate gaze paresis to the right. A lumbar puncture was normal. A left carotid arteriogram performed 14 hours after the onset of the patient's illness revealed nonfilling of the middle cerebral artery. Repeat arteriography 48 hours later demonstrated good filling of the middle cerebral artery. Clinically the patient made a good recovery and at the time of discharge demonstrated only a mild aphasic deficit (see Fig. 5 and 6).

Discussion

We have presented in this report three patients with angiographic evidence of disappearance of an intracranial arterial occlusion. In view of the cardiac dysrhythmias present in all three patients it is our opinion that the most reasonable explanation for the intracranial vascular occlusion is a cerebral embolus. Adams has suggested that in cerebral embolization there is subsequent fragmentation or dissolution of the embolus with its passage on into the cerebral microcirculation after initially occluding a major intracranial artery.[3] There has recently been speculation regarding the role of the naturally-occurring fibrinolytic mechanisms in the dissolution of intravascular occlusions, but insufficient evidence is available at the present time to allow a reasonable appraisal of this problem.

Review of the literature regarding angiographic studies in stroke cases reveals relatively few reports of angiograms performed within the first few hours or days after the onset of the acute stroke syndrome. Eiken, in a survey of 156 patients with strokes, examined 84 cases within the first seven days of onset but does not assess this group of patients separately from those evaluated at a later date.[4] He noted complete occlusion of the internal carotid in 25 cases and branch occlusion of the middle cerebral in eight additional cases. Fifteen instances of severe partial stenosis of a major intracranial artery were demonstrated, and atherosclerosis in the neck vessels was present in 86 of 156 patients studied. In a report of 152 patients with a diagnosis of stroke studied by bilateral carotid and vertebral arteriography, Meyer reports an approximately equal incidence of abnormalities in the carotid-middle cerebral system (315 abnormalities) and in the subclavian-vertebralbasilar system (303 abnormalities).[5] Approximately one half of the carotid arterial lesions were obstructive; of these, two thirds were extracranial and one third intracranial. Occlusion of the carotid artery in the neck occurred in ten patients (6.6%). No information can be extracted regarding relationship of time of angiography and time of onset of the stroke syndrome.

Conclusion

We would urge that the significance of atherosclerotic lesions in the neck vessels of patients with a stroke be evaluated with care. It is certainly conceivable that in some instances a 70-90% narrowing of a vessel lumen or a combination of scattered occlusive lesions might result in sufficient impairment of blood flow to part of the brain to result in a stroke syndrome. On the other hand, an equally attractive theory is that even a relatively small atherosclerotic plaque might serve as the site of a platelet and/or fibrin thrombus, which may then embolize into the distal intracranial circulation. We would, on the basis of our studies, suggest that failure to demonstrate intracranial vascular disease by arteriography or at autopsy in patients with encephalomalacia cannot preclude the possibility that for some period of time preceding the angiogram or the autopsy there did indeed exist an intracranial vascular occlusion of sufficient size or of sufficient duration to result in encephalomalacia.

Addendum

Following the preparation of this manuscript, similar reports concerning transient intracranial occlusions were published by P. F. Bladin in Radiology 82:615, 1964, by P. M. Dalal in Lancet 1:61, 1965 and by Zatz and Iannone in Neurology 15:389, 1965.

July—Saint Camillus de Lellis

In 16th century Italy Camillus founded a diligent and dedicated order known as Fathers of a Good Death, the members of which cared for the sick both in hospitals and at home. Legend has it that Camillus suffered most of his life from incurable abscesses on his feet; yet toward the end of his life, at age 64, when he was almost totally disabled, he continued his ambulatory ministrations to the sick even when obliged to crawl part of the way. July 18 is his day.

Famous Amulets

Catherine de Medici wore a piece of an infant's skin as a charm, and Lord Byron presented an amulet of this nature to Prince Metternich. Pascal died with some undecipherable inscription sewn into his clothes. Charles V always wore a sachet of dried silkworms to protect him from vertigo. The Emperor Augustus wore a piece of the skin of a sea calf to keep the lightning from injuring him, and the Emperor Tiberius wore laurel round his neck for the same reason when a thunderstorm seemed to be approaching.

Antagonism of Oleandomycin and Erythromycin

During Testing Against Staphylococci

MARSHALL H. SHORT, M.D.*
MELVIN NEREN, B.S.*
HORACE H. ZINNEMAN, M.D.*
Minneapolis, Minnesota

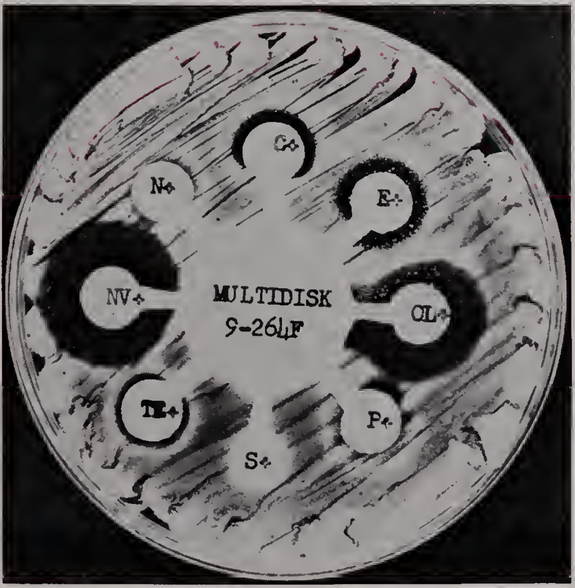

Fig. 1 — Appearance of antagonism between erythromycin and oleandomycin during routine antimicrobial sensitivity studies of staphylococci. Note the flattening of the zone of growth inhibition between the two discs marked E+ and O+.

THE FILTER paper discs which are used at the Minneapolis Veterans Hospital for routine determination of bacterial sensitivity to antimicrobial drugs** are arranged with those for oleandomycin and erythromycin adjacent to each other. One of the authors (M.N.) observed that certain cultures of staphylococci appeared to grow better in the zone between these two discs than in the rest of the area, thus flattening the circle of growth inhibition (Fig. 1).

This finding recalled to memory a report by Garrod,[4] stating that erythromycin and oleandomycin were less effective when used in combination than when employed singly in the treatment of certain resistant strains of staphylococci. In dealing with sensitive strains of staphylococci Elliott and Hall[3,5] observed that the bacteriostatic effect of oleandomycin was potentiated by erythromycin, and that the combination delayed emergence of resistant strains. In the studies of Elliott and Hall only one strain was more resistant to the mixture than to either antibiotic alone. Oskram[8] reported that the effect of this combination was unpredictable. The present study was undertaken in an attempt to clarify the effect of oleandomycin and erythromycin on staphylococci, singly and in combination.

Methods

The study of bacteriostatic effects of antibiotics employed the paper-strip agar-diffusion method described by Elek[2] and Dye.[1] White blotting paper (Grade A, Bermingham & Presser, New York, New York) was cut in strips of about 9 x 1 cm. for impregnation with oleandomycin and of about 5 x 1 cm. for impregnation with either penicillin or erythromycin. The following solutions were used for impregnation of the paper strips: penicillin G 100 units per ml., erythromycin 500 mcg/ml. and oleandomycin 500 mcg/ml. Penicillin was included as a control, since it is accepted that penicillin and oleandomycin show neither synergism nor antagonism. The degree of susceptibility of each of the 66 strains of staphylococci to penicillin was known.

---

*From the Departments of Laboratory and Medicine, Minneapolis Veterans Hospital and the University of Minnesota Medical School.

**Multidisk, Consolidated Laboratories, Chicago Heights, Illinois.

It was found convenient to make the antibiotic strips in quantity and to store them in sterile glass petri dishes at —20 C, since it was found that this did not result in an appreciable loss of antibiotic activity, even after several months of this cold storage.

Sixty-six strains of hemolytic, coagulase-positive staphylococci were available in pure culture from the clinical laboratories of the Minneapolis Veterans Administration Hospital over a period of several months. These organisms were grown overnight in beef-heart infusion broth, and this culture was used for heavy inoculation of petri plates with nutrient agar by means of sterile cotton swabs. The strips of blotting paper, which had been saturated with antibiotic solutions and allowed to dry, were laid on the freshly inoculated plates in a constant pattern, as seen in Figure 2. They were inspected after 24 hours' incubation at 37 C. Antagonism of two antibiotics was evident whenever the organism's growth was enhanced at the juncture of two paper strips. Addition of bacteriostatic effect was observed whenever the bacterial growth at the juncture of two strips was reduced beyond the inhibition of a single antibiotic (Fig. 2). Sensitivity studies by the tube-dilution method were done in 35 of the staphylococcal strains. Thirty of these had shown antagonism between oleandromycin and erythromycin by the paper-strip agar-diffusion method, whereas five had not. The tube-dilution sensitivity experiments were arranged as follows: Each organism was inoculated in four rows of tubes of nutrient broth. The first row of nine tubes contained decreasing concentrations of erythromycin; the following nine tubes contained decreasing concentrations of oleandomycin. A third row had decreasing concentrations of equal parts of oleandomycin and erythromycin. A fourth set of tubes also contained both antibiotics but were arranged so that the concentration of erythromycin was decreasing in successive tubes, whereas oleandomycin was increasing. The fourth row of tubes (E′ in Table 2) then contained the following concentrations of the two antibiotics:

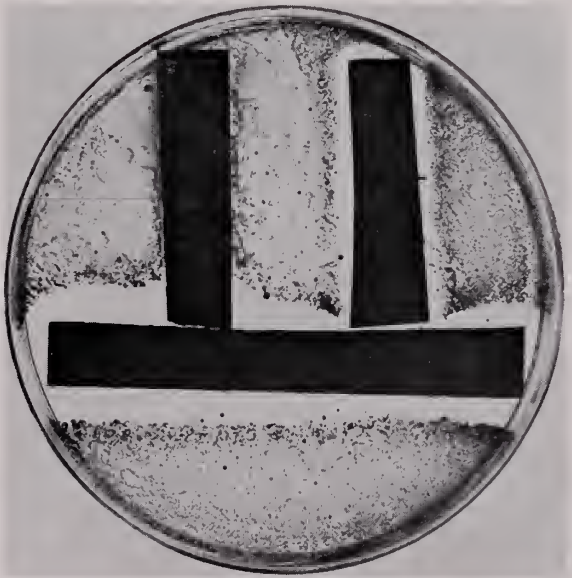

Fig. 2 — Agar diffusion studies. The horizontal paper strip was impregnated with oleandomycin, the vertical strip on the left with penicillin and that on the right with erythromycin. The bacterial growth at the juncture of the erythromycin and oleandomycin-impregnated paper strips is enhanced. There is an additive effect at the juncture of penicillin and oleandomycin.

	Erythromycin	Oleandomycin
Tube 1	50.0 mcg/ml.	0.19 mcg/ml.
Tube 2	25.0 mcg/ml.	0.39 mcg/ml.
Tube 3	12.5 mcg/ml.	0.78 mcg/ml.
Tube 4	6.25 mcg/ml.	1.56 mcg/ml.
Tube 5	3.12 mcg/ml.	3.12 mcg/ml.
Tube 6	1.56 mcg/ml.	6.25 mcg/ml.
Tube 7	0.78 mcg/ml.	12.50 mcg/ml.
Tube 8	0.39 mcg/ml.	25.00 mcg/ml.
Tube 9	0.19 mcg/ml.	50.00 mcg/ml.

The ninth tube dilution in column E′ of Table 2 has been omitted. O′ represents the reciprocal with decreasing concentrations of oleandomycin and increasing amounts of erythromycin, from the ninth to the second tube dilution. All tubes without growth were subcultured on blood-agar plates. When staphylococcal growth resulted, the antibiotic effect in the tube was considered bacteriostatic, whereas a sterile blood-agar plate signified bactericidal effect.

Results

Garrod's observation of varying degrees of resistance of staphylococci to erythromycin could be confirmed. In the case of erythromycin-resistant organisms a gradient zone could be observed at agar-diffusion in which the numbers of colonies decreased with increasing proximity of the erythromycin-impregnated paper strip, leaving a zone of 1-3 mm. immediately adjacent to the strips, which contained few isolated colonies. The same phenomenon was seen in the case of oleandomycin. It was absent in the case of penicillin-impregnated strips. There the colonies either grew right up to the margin of the strip, in the same density as in the rest of the petri dish, or there was a wide margin of growth inhibition which did not contain a single colony. Forty-nine of the 66 strains (76 per cent) showed resistance to penicillin and 34 (51 per cent) were resistant to erythromycin (Table 1).

There seemed to be no relation between the resistance to penicillin and erythromycin. Nineteen strains (29 per cent) were resistant to oleandomycin, and all of these were

also resistant to erythromycin (Table 1). Antagonism between erythromycin and oleandomycin by the agar-diffusion method was observed in 39 strains (59 per cent), which included all of the 34 erythromycin-resistant ones. By Dye's criteria there was no instance of synergism between oleandomycin and either erythromycin or penicillin. Only three (strain #23, 35 and 37) of the 30 strains which showed antagonism between erythromycin and oleandomycin by the agar-diffusion method failed to show evidence of this phenomenon by the tube-dilution method. Strains 7, 39 and 21, which were only moderately resistant, showed no inhibition when equal parts of erythromycin and oleandomycin were used, but showed some inhibition when the relative amounts of the two antibiotics were varied. There was little evidence of additive effect, as evident in Table 2 by comparison of column B (equal amounts of erythromycin and oleandomycin) with column E (erythromycin) and O (oleandomycin). Interestingly, the antagonism was most obvious in those strains which were relatively resistant to erythromycin but sensitive to oleandomycin. The five strains which did not show antagonism by agar diffusion also failed to show it by tube dilution.

Discussion

These experiments confirm previous observations by others[3,4,6] of the superior effectiveness of erythromycin over oleandomycin against susceptible strains of staphylococci. Resistant strains often showed this quality against erythromycin as well as oleandomycin, but there was no complete cross resistance as observed by others.[7] Twenty-one strains showed greater resistance to erythromycin than to oleandomycin, and it was this particular group which showed antagonism between erythromycin and oleandomycin. Three strains (strains 7, 10 and 43) showed approximately equal sensitivity to the two antibiotics, whereas six showed greater resistance to oleandomycin than to erythromycin (strains 19, 21, 23, 35, 37 and 39). Antagonism between erythromycin and oleandomycin was absent in six strains of staphylococci, which were sensitive to both drugs. One of them (strain 35) had shown antagonism on agar diffusion but not by tube dilution; the remaining five (Table 2-b) were in good agreement

The twofold dilutions were arranged as described under "Methods":

E signifies twofold dilutions of erythromycin from 50.0 mcg/ml. to 0.39 mcg/ml.

O stands for the same dilutions of oleandomycin

B contains equal amounts of erythromycin and oleandomycin, from 50.0 mcg/ml. each to 0.39 mcg/ml. each

E' contains erythromycin decreasing in twofold dilutions as under E, but oleandomycin increasing twofold from 0.19 mcg/ml. to 50.0 mcg/ml.

O' contains oleandomycin decreasing in twofold dilutions as under O, but erythromycin increasing twofold from 0.19 mcg/ml. to 50.0 mcg/ml.

The readings of each tube are reported as follows:

Blank spaces signify uninhibited growth.

s signifies bacteriostatic effect.

C denotes bactericidal effect.

with the agar-diffusion assay. There was only one sensitive strain, the culture of which was associated with a moderate antagonism between the two drugs (strain 43). The rest of the sensitive strains showed no antagonism.

The antagonism between oleandomycin and erythromycin, demonstrated in this series, had been seen to a much lesser degree in a previous investigation at this hospital.[3] The discrepancy may be due to a difference in the staphylococcal strains which were employed in the two studies. Most of the staphylococci in the study by Elliott and Hall[3] were sensitive to the two antibiotics, whereas the organisms of this series were preponderantly resistant to these drugs. The association of "antagonism" of erythromycin and oleandomycin does not then seem to be a phenomenon due to properties of the two drugs but rather to a quality of resistant staphylococci. Staphylococci resistant to erythromycin may elaborate a product which inactivates these structurally similar antibiotics. It is not likely to be penicillinase or chloramphenicolase, since this "antagonism" between erythromycin and oleandomycin is not present in association with staphylococci which are resistant to penicillin but sensitive to erythromycin. Perhaps this substance only binds these drugs. At this juncture one remembers the unusual protein-binding qualities of erythromycin, which, unlike most other antimicrobial drugs, is bound to orosomucoid in the alpha$_1$-globulins.[9]

Further studies have been initiated with the aim of clarification of the mechanism of this "antagonism" between erythromycin and oleandomycin. Meanwhile it should be borne in mind that the described "in vitro" phenomena may not be readily translated to conditions "in vivo."

Summary

In routine disc-sensitivity studies of a clinical hospital laboratory it was noticed that erythromycin and oleandomycin frequently seemed to inhibit each other, when tested against staphylococci.

Systematic studies by paper-strip agar diffusion and broth-tube dilution confirmed the observation.

Resistant strains of staphylococci usually were resistant to both drugs, but there was no complete cross resistance.

The "antagonism" between oleandomycin and erythromycin was seen predominantly in association with strains of staphylococci which showed either complete or partial resistance to one of these drugs, whereas sensitive strains failed to show this phenomenon to a significant degree.

The association of "antagonism" with resistant staphylococci suggests that this phenomenon is not an inherent quality of these two drugs, but is probably a product of resistant staphylococci which inactivates or binds both of these structurally similar antibiotics.

The Effect of Digitalis on the Electrocardiograms

Following Exercise In Normal Young Males*

JESSE BARRON, M.D.
ARTHUR C. KERKHOF, M.D.
CHARLES P. KOLARS, M.D.
ALEXANDER McEWAN, M.D.
Minneapolis, Minnesota

THIS STUDY was conducted on 23 males who were inmates of the Minnesota State Reformatory at St. Cloud, Minnesota. All men were volunteers; their ages ranged from 21 to 27. The purposes of the study were: (1) To evaluate the effects of digitalis on the exercise electrocardiogram, (2) To determine whether any changes would be produced in presumably normal young men, (3) If changes were produced, to note whether they were in any way similar to changes seen in so-called "positive" exercise tests done on people with coronary artery disease.

Materials and Methods

In the tables presented below, the term "ischemic change" indicates that a change was seen which could be confused with changes ordinarily considered significant in positive exercise challenge tests. A "nonspecific change" indicates changes which are

---

*This work was done under the auspices of the Cardiac Work Evaluation Unit of the Minnesota Heart Association which extends its appreciation for the co-operation of the State Reformatory at St. Cloud, Minnesota.

not diagnostic of those seen in coronary artery disease (T-wave and ST configuration changes which would not satisfy commonly accepted criteria of a positive exercise tolerance test).

During the entire six-week period of testing these men carried on their usual dietary programs and activities (including recreational football). A physical examination, a resting electrocardiogram and a 40-trip exercise test were done on each subject. During exercise a telemetered electrocardiographic monitoring of the V4 lead was carried out, followed by a post-exercise electrocardiogram.

Following this test each subject was given digitora, 1.28 grains (one CAT unit) per ten pounds of body weight over a three-day period, followed by a maintenance dose of one CAT unit daily. Three weeks after digitalization the subjects were re-examined and the previously described procedures repeated.

Digitalis was then stopped, and three weeks later the tests were repeated in an identical manner.

There was no significant subjective evidence of any digitalis toxicity. There was also no significant change in body weights during the entire six-week testing period, which would confirm the absence of any significant gastrointestinal complaints.

Results

(1) Of 23 subjects tested, one exhibited a positive electrocardiographic response to exercise before digitalis was administered.

(2) As can be seen from Table 1, 14 of the 23 subjects showed some change on their resting electrocardiogram after administration of digitalis. During the actual exercise period 17 of 23 showed changes, and following exercise 13 of the 23 showed changes.

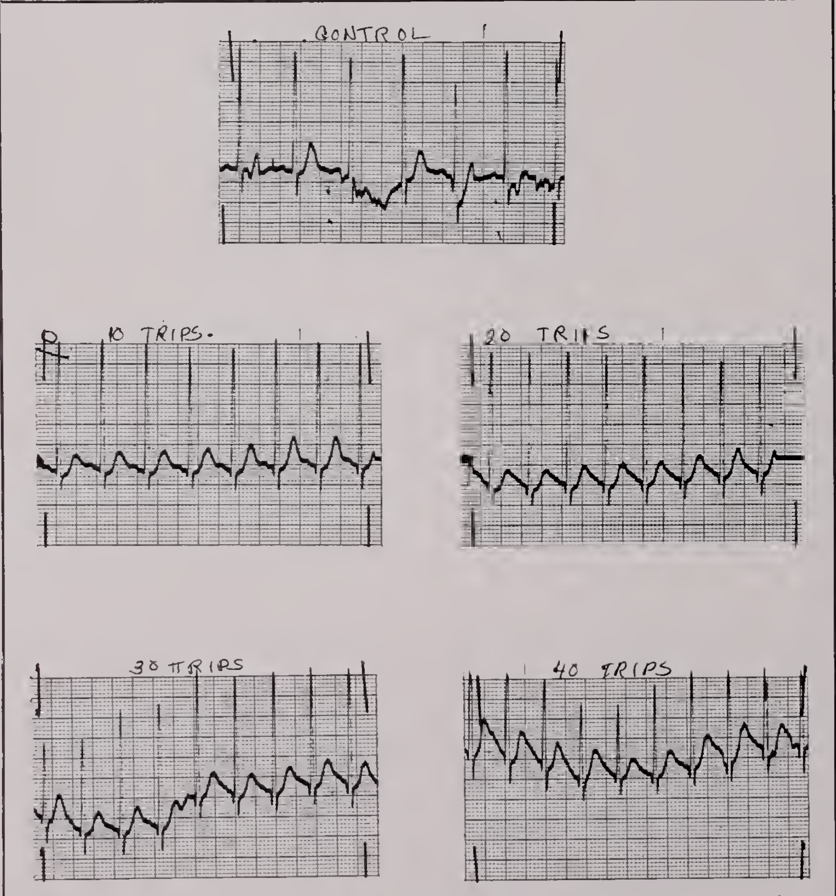

Fig. 1 — *(a)* Telemetered electrocardiogram taken during exercise prior to the administration of digitalis (V4 lead).

(3) In 10 subjects, changes were seen at the final examination three weeks after they had been off digitalis. Of these 10, seven were ischemic in nature and three were nonspecific in nature.

(4) As can be seen in Table 2, there was a significant increase in the average pulse rate during and following exercise. After exercise it returned promptly to the resting rate or below, indicating the basic circulatory integrity of the subjects tested. On digitalis the increase in rate was less pronounced; however, the average rate was initially slower and, in general, did not return to the resting state as promptly as in the control experiment. Three weeks after discontinuance of the digitalis, there was still a significant increase in rate during exercise and the post-exercise rate did not return to the pre-exercise rate.

(5) Considering the possibility that the electrocardiographic changes seen on digitalis may possibly have been related to rate, those patients who showed these changes on digitalis were evaluated with respect to rates as shown on Table 3. As can be seen, there is no significant deviation in this group from the total group.

Comment

It is apparent from these results that significant changes occur on both rest and exercise electrocardiograms following the administration of digitalis. In a remarkably large numer of instances, these changes are indistinguishable from the changes ordinarily associated with a positive exercise tolerance test (see Figure 1). It is also of significance that the changes persist up to at least three weeks following discontinuance of the digitalis in a significant number of cases. It

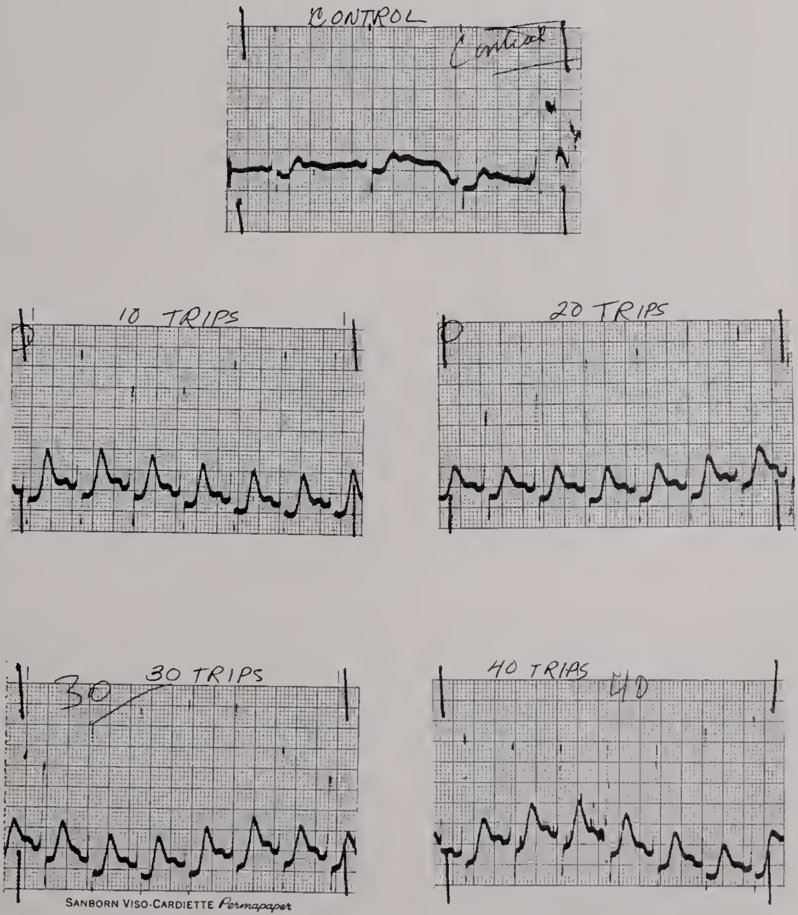

Fig. 1 — *(b)* Telemetered electrocardiogram taken after digitalis.

would seem that interpretation of an exercise test done on a person taking digitalis would be inconclusive because of the identical nature of the changes seen in presumably ischemic exercise electrocardiographic patterns and those patterns seen after the administration of digitalis in the absence of ischemia.

Conclusion

23 volunteers were studied to determine the effect of digitalis on the exercise electrocardiogram. A significant number of subjects showed changes which could be readily confused with those commonly attributed to coronary artery disease when subjected to electrocardiographic exercise tests.

Julian Huxley's Evaluation of Our Makeup*

"Our general construction is determined by the fact that we are made of living matter, must accordingly be constantly passing a stream of fresh matter and energy through ourselves if we are to live, and must as constantly be guarding ourselves against danger if we are not to die." Huxley analyzed us in the following manner, using approximate values:

5%—"consists of a tube with attached chemical factories, for taking in raw materials in the shape of food, and converting it.
2%—"consists of windpipe and lungs — for getting oxygen into our system . . . to burn the food materials and liberate energy.
10%—"consists of an arrangement for distributing materials — the blood and lymph, the tubes which hold them and the pump which drives them.
5%—"is devoted to dealing with waste materials — the kidneys and bladder . . . the lungs and skin.
40%—"is machinery for moving us about — our muscles.
20%—"is needed to support us and to give us mechanical leverage — our skeleton and sinews.
1%—"is set apart for giving us information about the outer world — our sense organs.
3%—"deals with the business of adjusting our behaviour — the ductless glands, the nerves, the spinal cord and the brain.
1%—"is set aside for reproducing the race.
7%—"is concerned with special functions like protection — the skin and some of the white blood corpuscles; or temperature regulations — the sweat glands.
10%—"consists of reserve food stores — fat."

---

Derivatively Speaking

Digitalis derives from digit (finger) because in German the foxglove from which the drug comes is called Fingerhut (thimble or finger-hat).

Habit is habit and not to be flung out of the window by any man, but coaxed downstairs a step at a time. — Mark Twain

Post Partum Tub Bath

Associated with Morbidity

JANE E. HODGSON, M.D.*
St. Paul, Minnesota
REGINALD A. SMITH, M.D.**
Rochester, Minnesota

THAT A variety of opinions exists regarding the value of routine post partum tub bathing was apparent after a review of this subject.[1] In view of the extensive program of hospital construction at the present time, it would seem important to resolve the question: Should all obstetrical units be designed with tub baths? Architects are constantly seeking advice from obstetricians as to the ideal number and type of bathing facilities required in obstetrical units.

All of us who use the tub bath[2] in the care of post partum patients have stated informally that such tub baths are safe, beneficial, and time-saving. However, an actual clinical analysis of the post partum course of patients receiving tub baths is not available. A study was therefore planned to evaluate the effect on post partum morbidity of a significant number of patients who had received such tub baths. The patients were drawn from the obstetrical services of the Charles T. Miller Hospital, St. Paul, Minnesota, and St. Marys Hospital, Rochester, Minnesota.

Procedure

Charles T. Miller Hospital, St. Paul, Minnesota. — On the first morning after delivery the patient was offered a 15-minute warm, soapy tub bath. This was continued twice daily until the patient was dismissed from the hospital. With this procedure it was possible to dispense with external douches, flushings, bed baths, and perineal lights. Over 20,000 patients have been treated with post partum tub baths by at least 90 per cent of the attending obstetrical staff of the hospital. The opinion of this group of obstetricians confirmed the impression that the procedure is safe. Since 1949, one of us (J. E. H.) has routinely prescribed such tub baths on the first post partum day for more than 3000 private obstetrical patients in the St. Paul area. All case histories since the year 1954 (2150 patients) were reviewed to evaluate morbidity after post partum tub bathing. Fever of 100.4° F. or higher at any time during the patient's hospitalization after receiving a tub bath was considered a sign of morbidity.

St. Marys Hospital, Rochester, Minnesota. — In 1951 post partum tub baths were commenced on a trial basis for the obstetrical patients of the majority of obstetricians practicing at St. Marys Hospital. The obvious benefits to the patient rapidly resulted in the adoption of this procedure as a routine for our normal post partum patients. Originally the baths were permitted on the third post partum morning only. After several years baths were commenced on the second morning and, of late, many patients are permitted baths on the first morning. Many patients are even permitted more than one bath per day.

---

*Charles T. Miller Hospital, St. Paul.

**Section of Obstetrics and Gynecology, Mayo Clinic and Mayo Foundation.

Charts of obstetrical patients were drawn at random and reviewed for elevations of temperature after the initial tub bath. Patients whose temperature was elevated above normal prior to the first tub bath were not considered suitable for study. Any oral temperature of 100.4° F. or higher was considered a sign of morbidity. The histories of 10,000 such patients were reviewed personally by one of us (R. A. S.).

Routine

After evaluation of this procedure in both centers, it was evident that a ratio of one tub per six patients was satisfactory.

In both hospitals tubs were prepared in a similar manner. The tub was scoured with an abrasive cleanser, rinsed with water, then washed with green soap and again rinsed. Five or six inches of warm water were drawn. The patient could then sit or lie in the tub, as she wished. The breasts were washed with soap during the bath. All douches, flushes, bed baths and perineal lights were eliminated during the hospitalization. Between tub baths the patient wore a sterile perineal pad.

Advantages of the Procedure

Increase in Patient's Physical Comfort

Physical comfort obviously was improved with elimination of lochia and perspiration from the perineum. The saponific action of the soap dissolves the dried adherent blood and serum from the perineal skin. Analgesics required for perineal discomfort were greatly reduced.

Reduction of Nursing Care

It is estimated that each patient requires at least one to two hours of nursing care per day for the usual and accepted perineal routine. The daily bed baths and series of four to six external flushings require a great deal of nursing time. In contrast, tub baths require less than 10 minutes. Within this time the nurse or aide can thoroughly clean and prepare the tub for the next patient.

Improvement of Bladder Function and Perineal Comfort

The effect of warm baths on improvement of bladder function is well known. The application of this principle to post partum care seems obvious. In the St. Paul study it was noted that the frequency of post partum catheterization was reduced. Reduction of perineal edema and anal discomfort is also noted in the study.

Morbidity

From the study of the 2150 obstetrical patients in the St. Paul area, over-all post partum morbidity was 2.42 per cent or 52 patients. All patients were submitted to tub baths within the first 24 hours after delivery. Of these, 1.58 per cent or 34 patients had fever of 100.4° F. or higher, possibly related to tub bathing; 0.84 per cent or 18 patients had fever considered unrelated to tub bathing.

From the study of 10,000 obstetrical patients delivered in the Rochester area, post partum morbidity was noted in 57 women or 0.57 per cent. Tub bathing was begun in a great proportion of patients 24 to 48 hours post partum. Thirty-two or 0.32 per cent had fever possibly related to tub bathing. Twenty-

TABLE
Causes of Morbidity

Possibly unrelated to post partum tub bathing	St. Paul	Rochester	Possibly related to post partum tub bathing	St. Paul	Rochester
Upper respiratory infection	2	10	Episiotomy infection	4	4
Mastitis (hormonal)	12	14	Endometritis	5	10
Phlebitis	1	1	Urinary tract infection	8	8
Dehydration (diabetic)	1	—	Hematoma	1	—
Toxemia	2	—	Breast abscess	1	—
			Unexplained	15	10
	18	25		34	32

five or 0.25 per cent had fever considered unrelated to tub bathing.

The causes of the post partum fever in the two groups of patients are outlined in the accompanying table.

Comment

In evaluating the post partum patients exhibiting morbidity, the extremely strict criteria for designation of morbidity should be stressed. In both groups all patients who had any temperature elevation to 100.4° F. or higher for any duration of time after receiving post partum baths were included. In spite of this, the percentage of morbidity is exceedingly low.

It should be noted that almost all post partum patients in the St. Paul group received tub baths, in contrast to the Rochester group, in which patients with upper respiratory infections, phlebitis, urinary catheters, post partum hypertension, hemorrhage, or debilitating conditions such as ulcerative colitis were excluded. Another difference in the two series was that patients in the St. Paul group began bathing on the first post partum day rather than the second or third. These two differences probably account for the apparently higher morbidity rate in the St. Paul series. Patients experiencing a brief elevation of temperature, often occurring 12 to 24 hours after the excitement and dehydration of labor, were of necessity included in the latter group, since baths were instituted immediately. In spite of these factors and the strict criteria for morbidity, the rates were extremely low in both groups.

Conclusions

Post partum tub bathing has been evaluated in two representative groups of patients totaling 12,150. The morbidity rate which could possibly be related to the tub bathing was exceedingly low (1.58 per cent and 0.32 per cent). In reply to the question: Should all obstetrical units be designed with tub baths? this study indicates a definitely affirmative answer. In the opinion of staff members of both institutions, a satisfactory ratio is one tub per six patents. Showers are of little use in an obstetrical or gynecological unit. The anatomy of the female is such that the genitalia cannot be adequately cleansed in the shower.

Tidbits of Medicine

A French drug dictionary quotes these unusual tasty tidbits of medicine that were recommended during the eighteenth century:

Burning hair, smelt by patients, will counteract the vapors. Moss of the human skull, human blood, and human urine all have their uses in medicine. The saliva of a robust young man is an antidote against the bites of serpents and mad dogs. Wax from the ears is good against whitlows. Nails from the fingers and toes, given internally either in substance or infused in wine, make a good emetic. Women's milk is pectoral, good in phthisis, and useful to apply to inflamed eyes. Fresh urine may be applied externally in gout and in skin complaints. Excrement of man can be applied to anthrax, plague bubos, and quinsies. Dried and powdered, it is recommended in epilepsy and intermittent fevers. Dose, one scruple* to a drachm.*,**

Primary Ileojejunal Ulcers

*A Possible Relation to Oral Enteric-Coated Potassium Therapy**

WILLIAM E. STEPHENS, M.D.
MAYNARD C. NELSON, M.D.
Minneapolis, Minnesota

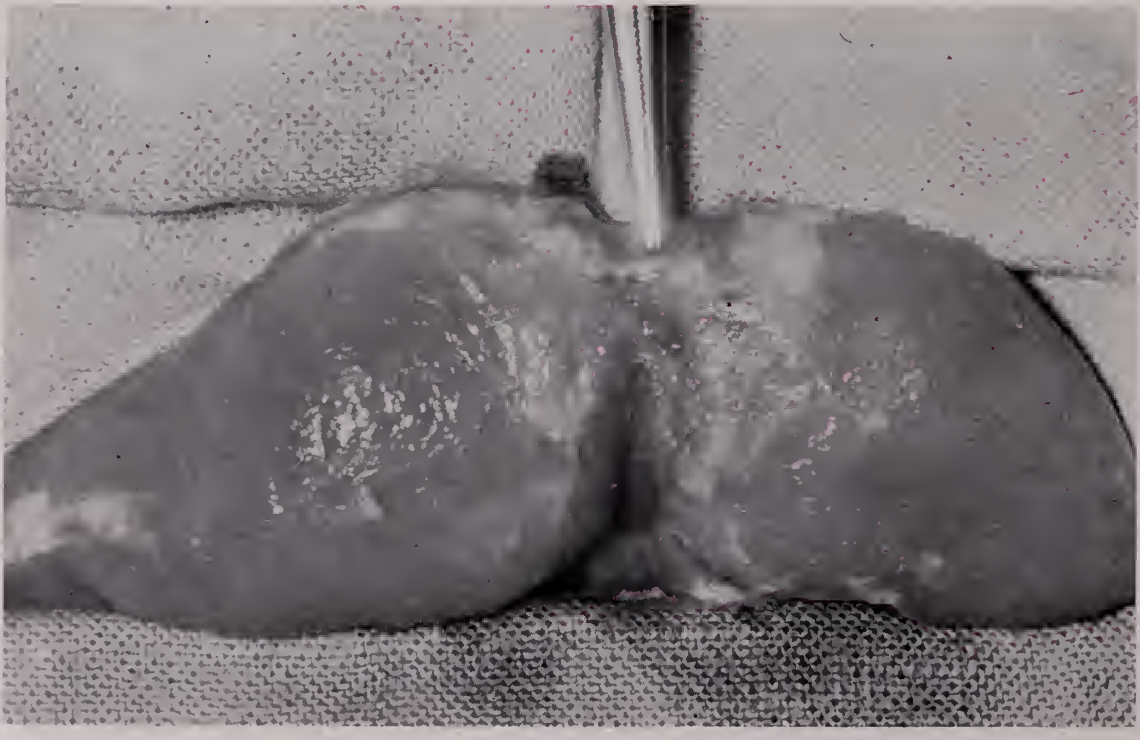

Fig. 2. Operative photograph showing the site of perforation.

SINCE 1805 WHEN Baillie[1] first described primary or nonspecific ulcers of the small bowel, occasional papers on the subject have appeared, but without a significant contribution as to probable etiology. Zollinger and Ellison reported the relationship of jejunal ulceration to islet cell tumors of the pancreas in 1955,[2] and no doubt a few of the cases previously reported as nonspecific ulcer of the small bowel fall into this category. Currently there are about 180 cases of nonspecific ulcer of the small bowel found on review of the literature.[1-23] The most recent report by Baker et al. documents an apparent increase in the incidence of the lesion as well as a possible correlation of it with oral enteric-coated potassium therapy.[23] Further support for these views was found in the five cases reported here, four of which had been on oral enteric-coated potassium therapy prior to surgical confirmation of the lesion, and all of which occurred in 1963 and 1964, the last two years of a ten-year review of the pathology records of three Minneapolis hospitals. All of the cases are consistent with the classification of nonspecific small bowel ulcer.

Pathologic Findings

Pathologically the lesion is a well-defined ulcer with underlying acute or chronic inflammatory reaction similar to peptic ulcer of the stomach. The more chronic cases show varying amounts of submucosal fibrosis and stricture. The adjacent bowel is normal, and mesenteric vascular and lymphoid change is significantly absent.

Symptoms

Symptoms are those of ulcer complication, i.e., partial intestinal obstruction, perforation, or hemorrhage. Pain is described as gnawing or cramping, and the site is most commonly periumbilical or just below and to the left of the umbilicus. Intermittent "bloating" is generally associated with loss of appetite, nausea, or vomiting.

Diagnosis

The diagnosis is rarely possible preoperatively, but it should be seriously entertained in cases of small bowel obstruction in the absence of hernia, previous abdominal surgery, and history consistent with gallbladder disease. Oral potassium therapy is an added clue that cannot be overlooked. Flat and upright X rays of the abdomen are of value in confirming intestinal obstruction or hollow viscus perforation. A barium study in those with vague or intermittent symptoms may confirm the presence of a distended loop proximal to the lesion, and occasionally a filling defect has been reported. Rarely is massive intestinal hemorrhage a finding, but anemia[5,7,21] and melena may occur. Guaiac positive stool was the most common positive laboratory finding in the report of Goehrs.[13]

Report of Cases

Case 1

This 63-year-old white female was admitted to the hospital January 2, 1962, with recurrent abdominal cramping, nausea and vomiting. Symptoms had been vague, transient, and recurrent over a three-year period. On preoperative study a single gallstone in a functionless gallbladder was found; and on one flat and upright X-ray examination there was a suggestion of partial small bowel obstruction. General physical examination was within normal limits, and the patient was on no medications.

At laparotomy January 3, 1962, a firm stenotic lesion of the small bowel 18 inches proximal to the ileocecal valve was found. The bowel distal to this point was reduced in calibre, but there was no significant proximal dilatation. The mesentery was normal. Further exploration was normal except for a diseased gallbladder containing a single ovoid 12x11x11 mm. cholesterol stone. Segmental resection and end-to-end anastomosis of the bowel along with cholecystectomy and incidental appendectomy was done. Recovery was uneventful.

Pathologically the lesion showed mucosal ulceration, submucosal acute and chronic inflammatory cells and fibrosis, consistent with nonspecific ulceration of the small bowel.

Case 2

A 29-year-old housewife was admitted to the hospital April 3, 1964, with cramping lower abdominal pain, abdominal distension, lower abdominal tenderness, hyperactive bowel sounds with intermittent rushes and rectal tenderness on the left. Flat and upright films of the abdomen revealed findings consistent with small bowel obstruction. Symptoms subsided overnight and she was discharged.

Additional history revealed that in January, 1964, she had been taking, for severe headaches, an oral enteric-coated diuretic with potassium, resulting in symptomatic improvement in the frequency of her headaches. Ten days before her admission, cramping abdominal pain began.

---

*Read before the Minneapolis Surgical Society.

She was readmitted April 13, 1964, with identical symptoms which did not subside. Therefore, on April 15, 1964, laparotomy was carried out.

At surgery a 5-mm. area of stenosis was found in the ileum three feet proximal to the ileocecal valve. The bowel distal to the lesion was collapsed; proximal to the lesion it was dilated and edematous. A 9-cm. segment of small bowel was resected and an end-to-end anastomosis done. Recovery was uneventful and the patient has remained well to date.

The resected specimen showed mucosal ulceration and an acute submucosal inflammatory infiltrate at the site of the lesion (Fig. 1). The lesion was consistent with the diagnosis of nonspecific ulcer of the small bowel.

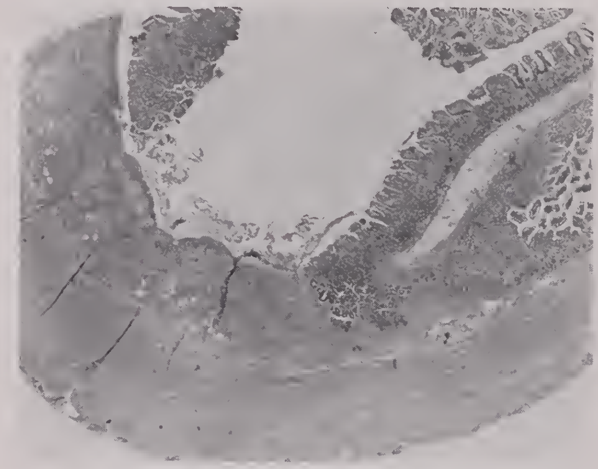

Fig. 1. Case 2. A section showing the mucosal ulcer, and submucosal acute infiltrate and edema.

Case 3

A 24-year-old housewife was admitted to the hospital with complaints of marked bloating and persistent generalized abdominal pain which had had sudden onset after the evening meal the previous day.

Examination revealed abdominal distension, minimal lower abdominal guarding and rebound tenderness. The temperature was 100.2. White blood count was 20,000 with 92% polymorphonuclear cells. As culdoscopy was being done, an abundant amount of thin, greenish-white, odorless fluid was released. Flat and upright films of the abdomen showed free air under both leaves of the diaphragm.

Past history revealed a sixty-five-pound weight gain in a post-partum period one year before the present illness, and in an effort to reduce weight an oral diuretic with potassium was taken in November, 1963. In February 1964, the patient went on a self-prescribed grapefruit and eggs diet. Two days later she developed severe bloating, abdominal pain, and nausea. Symptoms subsided with resumption of a normal diet and discontinuation of the diuretic. She claimed she never resumed the diet or took any diuretic in the 60-day interval from that time to the onset of the present illness.

Laparotomy April 24, 1964, revealed a perforation at the site of a circumferential narrowing in the lower jejunum (Fig. 2). The greenish-milky fluid aspirated at culdoscopy was present over the loops of bowel in the lower half of the abdomen and in the pelvis. There was also some distension of the small bowel proximal to the lesion; otherwise, the small bowel and mesentery were normal. A 12-cm. segment of small bowel was resected and an end-to-end anastomosis done. Recovery was uneventful.

Examination of the specimen revealed a circumferential mucosal ulceration with a small perforation on the antimesenteric border. Microscopically, the lesion was an acute ulcer with an acute inflammatory infiltrate limited to the wall at the site of perforation (Fig. 3).

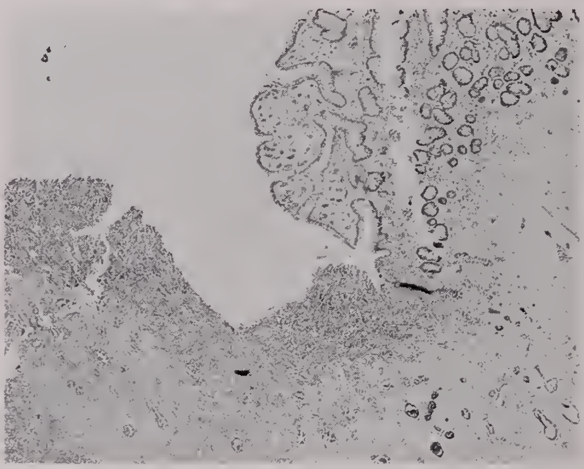

Fig. 3. Case 3. Section showing the acute ulcer with perforation and adjacent normal small bowel.

Case 4

A 59-year-old male was admitted to the hospital May 3, 1964, with cramping abdominal pain of two days' duration. Two weeks prior to admission he had had an episode of weakness, faintness and transient numbness of the right leg, with a similar episode the following day. On examination there was no neurological deficit. These episodes were thought to represent mild cerebrovascular accidents. An enteric-coated diuretic containing potassium was prescribed. For two days after the medication was started the patient complained of mild abdominal cramping, but was asymptomatic during the remaining ten-day interval before the onset of the present illness. Examination revealed a blood pressure of 140/90. The abdomen was distended and there was tenderness to the left of the umbilicus. Bowel sounds were slightly hyperactive. White blood count was 11,900 with 90% polymorphonuclear cells. Flat and upright films of the abdomen were consistent with a partial small-bowel obstruction. Symptoms subsided with rest and intravenous fluid therapy, and the patient was discharged. Symptoms recurred after discharge with almost daily mild abdominal cramping, and on May 25, 1964, he was readmitted with recurrent small bowel obstruction. The diuretic with potassium was taken during the interval between hospital admissions.

At laparotomy May 25, 1964, a 5-mm.-long stenosis of the ileojejunal area of the small bowel was resected and an end-to-end anastomosis was done. Recovery was uneventful, and the patient has remained well to date.

Sections of the lesion revealed a circumferential mucosal ulceration with both acute and chronic infiltrate at the ulcer base. Submucosal edema and fibrosis were noted. The lesion was considered consistent with a nonspecific ulcer of the small bowel.

Case 5

A 46-year-old male was admitted to the hospital November 7, 1963, with constant right lower abdominal pain and frequent loose stools of one month's duration. One year previously the patient had undergone an extensive hospital evaluation for episodes of dizziness, weakness, palpitation, and sweats involving the head and neck, thought possibly to be due to pheochromocytoma. Tests failed to confirm this impression, however. Because of hypertension (180/110) an enteric-coated diuretic containing potassium was prescribed in December 1962. The patient developed right lower quadrant pain in March 1963, occurring two to three times a week and lasting from a few minutes to one and one-half hours. He was hospitalized May 2, 1963, because of the abdominal pain. Studies were negative except for the admission flat and upright films of the abdomen which showed small bubbles of gas scattered throughout the small bowel. The diuretic was continued after discharge from the hospital.

Laparotomy was done November 8, 1963. A stenotic lesion in the ileum 18 inches proximal to the ileocecal valve was resected and end-to-end anastamosis was done.

There was a 1-cm. circumferential mucosal ulcer at the site of the lesion. Sections showed an acute inflammatory base, and also submucosal edema and fibrosis.

Following discharge from the hospital this patient resumed therapy with the enteric-coated diuretic with potassium until July 1964, without further abdominal complaints.

Discussion

With the advent of an apparent increase in incidence of nonspecific small bowel ulceration and a suggestive correlation with the ingestion of a chemical agent in a high percentage of the recently reported cases, further detailed documentation of similar cases is essential. Four of the five reported cases in this series were taking or had been taking an enteric-coated oral diuretic containing 500 mgm. of potassium chloride prior to the onset of symptoms. Three different preparations were represented. All five cases occurred one to three years after the introduction in this area of enteric-coated diuretic preparations containing potassium chloride, whereas none were found in the pathology records of the three hospitals in the prior eight years of a ten-year review.

Duration of therapy prior to the onset of symptoms varied from a few days to three months. In one case acute symptoms developed while on potassium therapy and subsided after cessation of medication, only to recur two months later.

Duration of symptoms varied from one to nine months before a surgical diagnosis was made. Significantly, three of the patients were healthy individuals with no cardiovascular disease. Two were young housewives in their twenties. The earlier literature on nonspecific small bowel ulceration showed a predominance of perforated ulcers (81% of 130 cases reviewed by Evert in 1948).[6] Cases reported after 1960 appear predominantly as partial intestinal obstructions; stenosis is the prominent feature at surgery. Nineteen of the last twenty-three cases presented with symptoms of intestinal obstruction. The other four with perforations gave histories suggestive of pre-existing partial obstruction and had some degree of stenosis noted at the site of perforation. With this possible exception the lesions occurred predominantly in the lower jejunum or ileum and were pathologically similar to those previously reported. Surgical management was indicated in those with complications of the ulcer; morbidity and mortality were low.

Conclusion

Although there is suggestive evidence that oral therapy with enteric-coated potassium medications may be a contributing etiological factor, one case in this series and all of the cases prior to the introduction of this form of therapy must be explained on some other basis.

Acknowledgment

The authors are indebted to Dr. B. D. Mitchell and Dr. D. J. Moos for the privilege of reporting cases 5 and 4.

WHAT'S YOUR DIAGNOSIS?

A fifty-year-old, previously well railroad conductor noted the onset of mild "burning" distress across the mid-abdomen a week prior to admission. Three days prior to admission he developed intermittent crampy pains in the left upper abdomen. There was no nausea, vomiting or loss of appetite. His bowels continued to move with a normal-appearing stool. His past history was negative except for rheumatic fever at age thirteen and a hemorrhoidectomy a year previous to admission.

Physical examination was negative except for left upper abdominal tenderness without distention, rigidity, or rebound. There was mild left costovertebral angle tenderness.

Laboratory studies showed a hemoglobin of 14 gm %, a WBC of 7,000 with a differential of 57% pmn's and 39% lymphocytes. The sedimentation rate was 9 mm. in one hour. The urinalysis was normal. Serum amylase was normal. X-rays of the chest and abdomen were normal. The ECG was normal. Upper GI x-rays with small bowel follow-up were normal. On the third hospital day the diagnosis became evident.

What is your diagnosis? Turn to page 918.

LOMOTIL—*Pharmacologic Activity.*

The significant pharmacologic actions of Lomotil are summarized as follows:

Evidence indicates that Lomotil acts directly on the intestinal musculature to inhibit excess peristalsis.

Lomotil is not known to inhibit nonpropulsive intestinal movements.

Roentgenograms demonstrate that this activity occurs within two hours after oral administration and persists for at least six hours.

Comparative studies in the rat show Lomotil to be more effective in inhibiting fecal excretion than either codeine or morphine.

Analgesic, anticholinergic, mydriatic and gastric secretory effects have not been significant.

Reduction of propulsive motility with Lomotil relieves spasm and cramping, allows physiologic absorption of fluid and reduces frequency of evacuations to provide prompt, symptomatic control of virtually all diarrheas.

LOMOTIL® tablets liquid

Each tablet and each 5 cc. of liquid contains:
diphenoxylate hydrochloride .... 2.5 mg.
(Warning: May be habit forming)
atropine sulfate .... 0.025 mg.

slows propulsion · relieves distress · stops diarrhea

Precautions: Lomotil is an exempt narcotic preparation of very low addictive potential: more than three million prescriptions have now been written for Lomotil. Recommended dosages should not be exceeded. Lomotil should be used with caution in patients with impaired liver function and in patients taking addicting drugs or barbiturates.

Side Effects: Side effects are relatively uncommon but among those reported are gastrointestinal irritation, sedation, dizziness, cutaneous manifestations, restlessness and insomnia.

Dosage: For full therapeutic effect – Rx full therapeutic dosage. The recommended initial daily dosages, *given in divided doses,* until diarrhea is controlled, are:

Children:
3 to 6 months–3 mg. (½ tsp.* t.i.d.)
6 to 12 months–4 mg. (½ tsp. q.i.d.)
1 to 2 years–5 mg. (½ tsp. 5 times daily)
2 to 5 years–6 mg. (1 tsp. t.i.d.)
5 to 8 years–8 mg. (1 tsp. q.i.d.)
8 to 12 years–10 mg. (1 tsp. 5 times daily)

Adults: 20 mg. (2 tsp. 5 times daily or 2 tablets 4 times daily) **Based on 4 cc. per teaspoonful.*

Maintenance dosage may be as low as one fourth the therapeutic dose.

Lomotil is a brand of diphenoxylate hydrochloride with atropine sulfate; the subtherapeutic amount of atropine is added to discourage deliberate overdosage.

Small Bowel Ulcers

A SCIENTIFIC presentation in this issue of Minnesota Medicine* presents five patients recently operated upon for stenosing ulcers of the small intestine. The authors call attention to the possible relationship of these ulcers to therapy with oral enteric-coated potassium chloride medications.

During recent months several pharmaceutical companies have produced medications combining hydrochlorothiazide and potassium chloride in a common enteric-coated tablet. This type of combined therapy was implicated as a causative factor in small bowel obstruction in November 1964, in a scientific article in the Journal of the American Medical Association by Baker, Schrader, and Hitchcock. These authors presented 12 patients with nonspecific ulceration and stenosis of the small intestine, 11 of whom had received medication with the combined hydrochlorothiazide and potassium chloride tablets. The 11 cases in the November report occurred over a period of 15 months, and statistical analysis indicated that patients on potassium-containing, enteric-coated medications have a significantly higher risk for development of an ulcerating and obstructing small bowel lesion than other patients receiving potassium chloride medication without the enteric coating.

The clinical study presented in this issue of the journal adds to the evidence that enteric-coated potassium chloride is a potentially dangerous form of potassium therapy. When the potassium salts are suddenly released to the mucosa in high concentration at a specific pH of the intestinal content, cellular damage leads to ulceration and fibrosis. Evidence garnered from several parts of the world now indicate this to be a problem wherever this form of potassium therapy is used.

Physicians at the Hennepin County General Hospital are now encouraged to prescribe hydrochlorothiazide as a single preparation, and to provide supplemental potassium as a separate medication dissolved in orange juice or some other fruit juice. At this time all evidence indicates that hydrochlorothiazide alone does not cause intestinal ulceration and stenosing with subsequent obstruction. Also, present evidence indicates that potassium chloride dissolved in a liquid does not harm the intestine. Practicing physicians are alerted to the possible dangers inherent in the combined form of therapy.

Claude R. Hitchcock, M.D.
Minneapolis, Minnesota

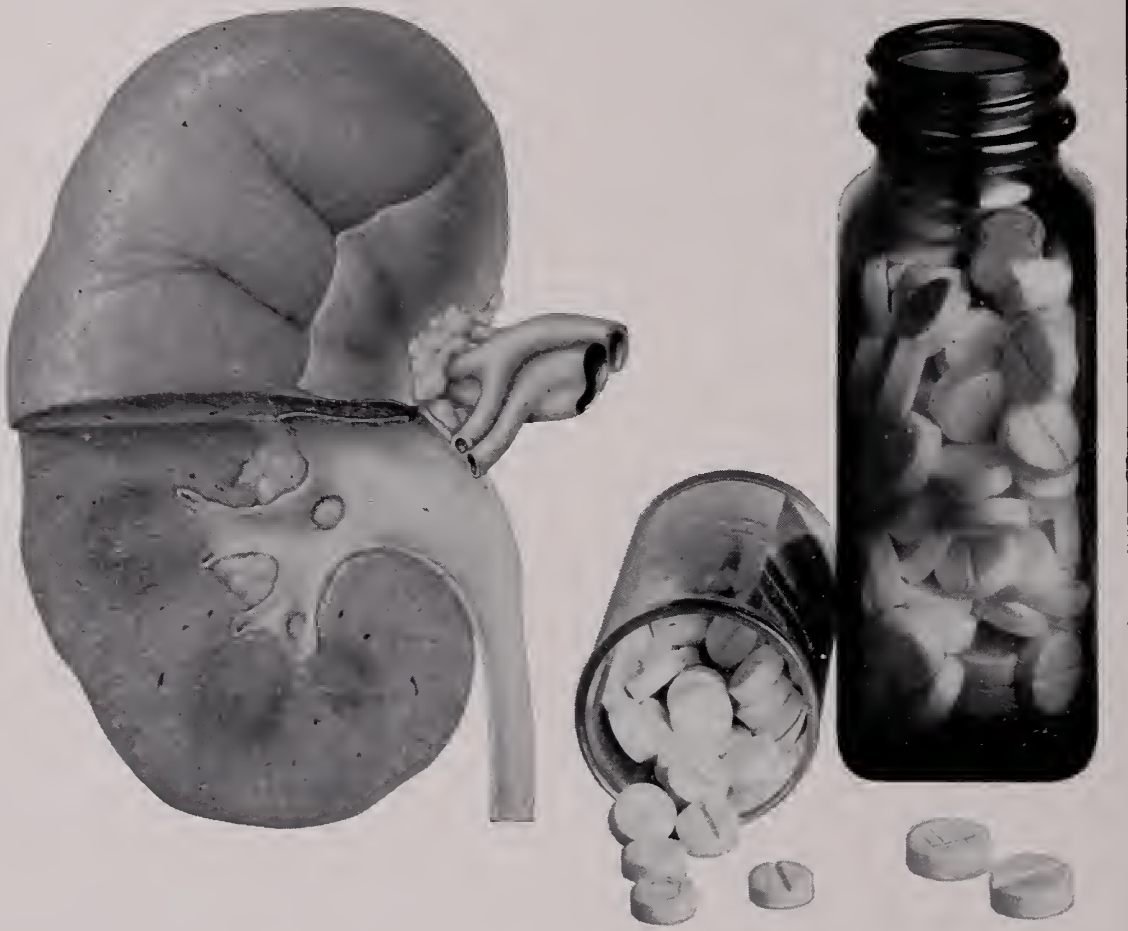
at Merck Sharp & Dohme...



understanding... precedes development

The development of chlorothiazide and probenecid were events of major importance, but perhaps even more important for the future was the Renal Research Program by which they were developed. When Merck Sharp & Dohme organized this program in 1943, it was expressing in action some of its basic beliefs about research:

- Many problems connected with renal structure and function were still undefined or unsolved. The Renal Research Program would begin its basic research in some of these problem areas.
- From knowledge thus acquired might come clues to the development of new therapeutic agents of significant value to the physician.

For example, the Renal Research Program put fifteen years into this search before chlorothiazide became available. But because these years had first led to a greater understanding of basic problems, the desired criteria for chlorothiazide existed before the drug was developed.

Along with other research teams at Merck Sharp & Dohme, the Renal Research Program continues to add new understanding of basic problems—understanding which will lead to important new therapeutic agents.

where today's theory is tomorrow's therapy

Blood Transfusion and the Clinician

Within the past two decades the technique of blood transfusion has been developed to a point where it is regarded by many as a routine procedure, and the ever threatening dangers are sometimes not fully appreciated. Elsewhere in this journal* Dr. Huestis emphasizes some of the problems and pitfalls with which the laboratory of a blood bank has to deal on a daily basis.

Incompatibility of blood types, however, is only one of the dangers accompanying blood transfusion. The danger of homologous serum hepatitis not only exists, but at the present time can be neither completely prevented nor controlled. Other consequences, such as overloading of the recipient's circulation, do not concern the blood bank directly and are the responsibility of the clinician.

The overwhelming majority of hemolytic reactions due to the transfusion of incompatible blood are not the result of laboratory errors but fall in the category of "clerical error."

Within the blood-bank laboratory they can be avoided if the bookkeeping system is as simple as it is rigidly controlled. Human errors will increase in direct proportion to multiple transcriptions of data. The less copying and transcription the less error! Most blood banks have recognized this problem and eliminated or minimized its dangers. However, a well organized and operated blood bank will be powerless to prevent a tragically high incidence of transfusion reactions if it has to operate within a clinical organization which permits laxity and carelessness on wards and in operating rooms, because most "clerical errors" occur outside the blood bank proper. The most common errors arise in the following situations:

1. Obtaining the recipient's blood sample, the "pilot tube." All efforts should be made to have blood-bank personnel obtain the patient's blood sample rather than physicians or general laboratory personnel. If circumstances necessitate the drawing of a pilot sample by persons other than blood-bank personnel the patient's full name, hospital number, the date and initials of the individual who obtained the "pilot" sample, must be written in ink on a label, which is firmly affixed to the glass tube, not merely rolled or folded around it.

2. Only blood-bank personnel may issue blood. Access to blood-bank refrigerators must be strictly forbidden to anyone else.

3. If several blood units were issued for a patient and temporarily stored in a ward refrigerator, we would create a situation which facilitates the confusion of blood units intended for different patients. Therefore, only one unit should be issued for any one patient at a time for ward use, even though successive transfusions are planned. In the case of surgery all units which have not been used during operation, will be returned to the blood bank immediately after termination of surgery. The loss of time spent in repeated trips of ward attendants to the blood bank, will be rewarded by a decrease of transfusion catastrophes.

4. Improper identification of the recipient has been the most important clerical error. The recipient will be identified not only by full name but also by hospital number, and these data will have to be identified on the patient's identification bracelet (or bed tag), the label on the blood unit and the request sheet. The transfusion may be undertaken only if all data agree.

Other precautions will be followed as a matter of routine. The sample of a patient's blood "pilot tube" may be used for cross-matching only for a period of 3-5 days. A fresh "pilot" will have to be employed for any transfusion thereafter. After termination of each transfusion the empty bottle or plastic bag must be returned to the blood bank, where it will be kept for 48 hours. Late transfusion reactions, particularly those in which bacterial contamination of the donor blood is suspected, may then be investigated

**Depend on low-cost,
low-dosage Prolixin
— once-a-day**

Prolixin is a dependable tranquilizer that provides your patient with low cost therapy. No other tranquilizer costs less. Safe and convenient for office use—Prolixin in a single daily dose provides prolonged and sustained action. Markedly low in toxicity and virtually free from usual sedative effects —Prolixin is indicated for patients who must be alert. Clinical experience indicates fluphenazine hydrochloride is especially effective in controlling the symptoms of anxiety and tension complicating somatic disorders such as premenstrual tension, menopause, or hypertension—also useful for anxiety and tension due to environmental or emotional stress. When you prescribe Prolixin you offer your patient effective tranquilization that is low in cost, low in dosage and low in sedative activity.

THE SQUIBB TRANQUILIZER

WHEN TRANQUILIZATION WITHOUT SEDATION IS DESIRABLE, TRY

PROLIXIN®

SQUIBB FLUPHENAZINE HYDROCHLORIDE

SIDE EFFECTS, PRECAUTIONS, CONTRAINDICATIONS: As used for anxiety and tension, side effects are unlikely. Reversible extrapyramidal reactions may develop occasionally. In higher doses for psychotic disorders, patients may experience excessive drowsiness, visual blurring, dizziness, insomnia (rare), allergic skin reactions, nausea, anorexia, salivation, edema, perspiration, dry mouth, polyuria, hypotension. Jaundice has been exceedingly rare. Photo-sensitivity has not been reported. Blood dyscrasias occur with phenothiazines; routine blood counts are recommended. If symptoms of upper respiratory infection occur, discontinue the drug and institute appropriate treatment. Do not use epinephrine for hypotension which may appear in patients on large doses undergoing surgery. Effects of atropine may be potentiated. Do not use with high doses of hypnotics or in patients with subcortical brain damage. Use cautiously in convulsive disorders.

AVAILABLE: 1 mg. tablets. Bottles of 50 and 500.

For full information, see your Squibb Product Reference or Product Brief.

SQUIBB Squibb Quality—the Priceless Ingredient

with competence.

Whenever a transfusion reaction is suspected the following steps should be taken:

1. If a hemolytic reaction is suspected (tingling sensation, pain in chest and back, fever, chill, tachycardia, tachypnea, hypotension, etc.) the transfusion is to be stopped immediately. Hydrocortisone may be administered intravenously in an attempt to minimize the hemolytic reaction. Twenty-five grams of mannitol may be infused intravenously in order to promote diuresis and dilution of hemoglobin in the renal tubules. The administration of mannitol may be repeated if successful.

2. The blood bank is to be notified immediately.

3. A sample of the patient's blood will be collected in a tube which contains an appropriate anticoagulant. Although these tubes are available commercially as rubber-stoppered vacuum tubes, artificial hemolysis should be avoided by releasing the vacuum and transferring the blood gently from the syringe, avoiding turbulence or the formation of air bubbles. The plasma of this specimen will then be used for the quantitative determination of free plasma hemoglobin. This will be repeated after 4 and 12 hours.

4. Another blood sample will be used for the determination of serum bilirubin and blood urea nitrogen. This will be repeated after 12 and 24 hours.

5. Blood cultures will be obtained and the material incubated at 37 C and 4 C under aerobe and anaerobic conditions.

6. The patient's urine will be collected on a 24-hour basis for determination of urine hemoglobin as well as the quantity of urine output.

7. The blood unit which was involved in the suspected transfusion reaction will be returned to the blood bank for verification of the crossmatch as well as for bacterial culture at 37 C and 4 C under aerobe and anaerobic conditions. Bacteremia due to contamination by donor blood can be assumed only if the same organism is cultured from the donor bottle as well as from the recipient's blood.

Although the danger of serious transfusion reactions can be minimized by the combined efforts of laboratory and the clinical services, a rare human error cannot be eliminated completely. Whenever such an accident occurs the responsibility will be easier to shoulder if the transfusion was "necessary," i.e., if it was administered for the type of blood loss or anemia which could not have been remedied satisfactorily in any other way.

Peritonitis and Gas Gangrene

Although many advances in the diagnosis and treatment of various types of infections have been made in the past two decades, infections within the peritoneal cavity are difficult to study bacteriologically and therefore difficult to treat effectively. If the abdominal cavity is surgically explored and if adequate fluid or tissue is obtained for culture, the etiologic agent usually can be identified within a few hours or a few days. However, surgical exploration is not always advisable and, even after laparotomy, a period of time often passes before cultural data are available. During this interval the cause and, therefore, the correct management of the infection are not apparent. To date there is no single antibiotic agent or any combination of agents that is effective against all of the various strains of bacteria that may cause peritonitis. For these reasons, continuing study of the bacteriologic and pathologic aspects of peritoneal infections is imperative.

The spectrum of organisms that may produce peritonitis is wide, and the infection may range from a very acute, rapidly lethal process to a low-grade indolent infection. In most instances, the infections are due to a mixture of organisms. The flora of the intestinal tract participate in many of these.

one place your hay-fever patient doesn't need **ORNADE®** (unless he has a cold)

Trademark

Each capsule contains 8 mg. of Teldrin® (brand of chlorpheniramine maleate), 50 mg. of phenylpropanolamine hydrochloride, and 2.5 mg. of isopropamide, as the iodide.

...but if your patient can't get away from hay fever, relieve sneezing, weeping and nasal congestion for 24 hours with one 'Ornade' Spansule® brand sustained release capsule q12h

Summary of contraindications, cautions and side effects: Do not use in patients with glaucoma, prostatic hypertrophy, stenosing peptic ulcer, pyloroduodenal obstruction, or bladder neck obstruction. Use with caution in the presence of hypertension, hyperthyroidism, or coronary artery disease. Drowsiness; excessive dryness of nose, throat or mouth; nervousness or insomnia may occur on rare occasions but are usually mild and transitory.

Before prescribing, see SK&F product Prescribing Information.

Smith Kline & French Laboratories SK&F

Enteric bacilli are frequently present, but in many instances, Bacteroides and various strains of Clostridium and enterococcus are considered more important in the pathogenesis. Some of these organisms are capable of producing gas in the tissues. E. coli and certain species of Clostridium may be responsible for considerable amounts of gas. The detection of gas in infected tissues, therefore, is not necessarily a sign of gas gangrene due to Clostridium organisms since E. coli and other organisms are capable of producing gas. Of course, the possibility of gas gangrene due to species of Clostridium always must be considered seriously, since disregard for this type of infection would be disastrous.

When Clostridium organisms are cultured from the human body, the question frequently arises as to whether antitoxin should be given. Gas gangrene is a virulent and frequently fatal disease. All measures that might affect the outcome favorably must be employed. However, gas gangrene antitoxin is derived from horse serum, and its use may be accompanied by any of the hypersensitivity reactions so often associated with the administration of horse serum to man. Clostridium organisms are normal inhabitants of the intestinal tract and at times can be cultured from tissues in which there is no evidence of gas gangrene and in which this infection does not develop. Careful physical examination and experienced clinical judgment are necessary in the determination of the type of treatment that should be given when the "gas gangrene" strains of Clostridium are cultured from tissues.

Blood cultures should be obtained from all patients with peritonitis. If tissue or fluid from the peritoneum cannot be obtained for culture, blood cultures often provide essential bacteriologic information regarding the etiologic organism or organisms. Furthermore, if bacteremia is present, the possibility of impending or associated bacteremic shock must be considered, and the patient must be managed accordingly.

In recent years, the use of hyperbaric oxygen in the treatment of infection due to anaerobic or microaerophylic organisms such as species of Clostridium has been studied in a small number of infections. Encouraging results in the treatment of gas gangrene infections have been reported. Unfortunately, the use of hyperbaric oxygen is associated with certain hazards. Therefore its widespread use in the treatment of infections must await further study by experienced investigators.

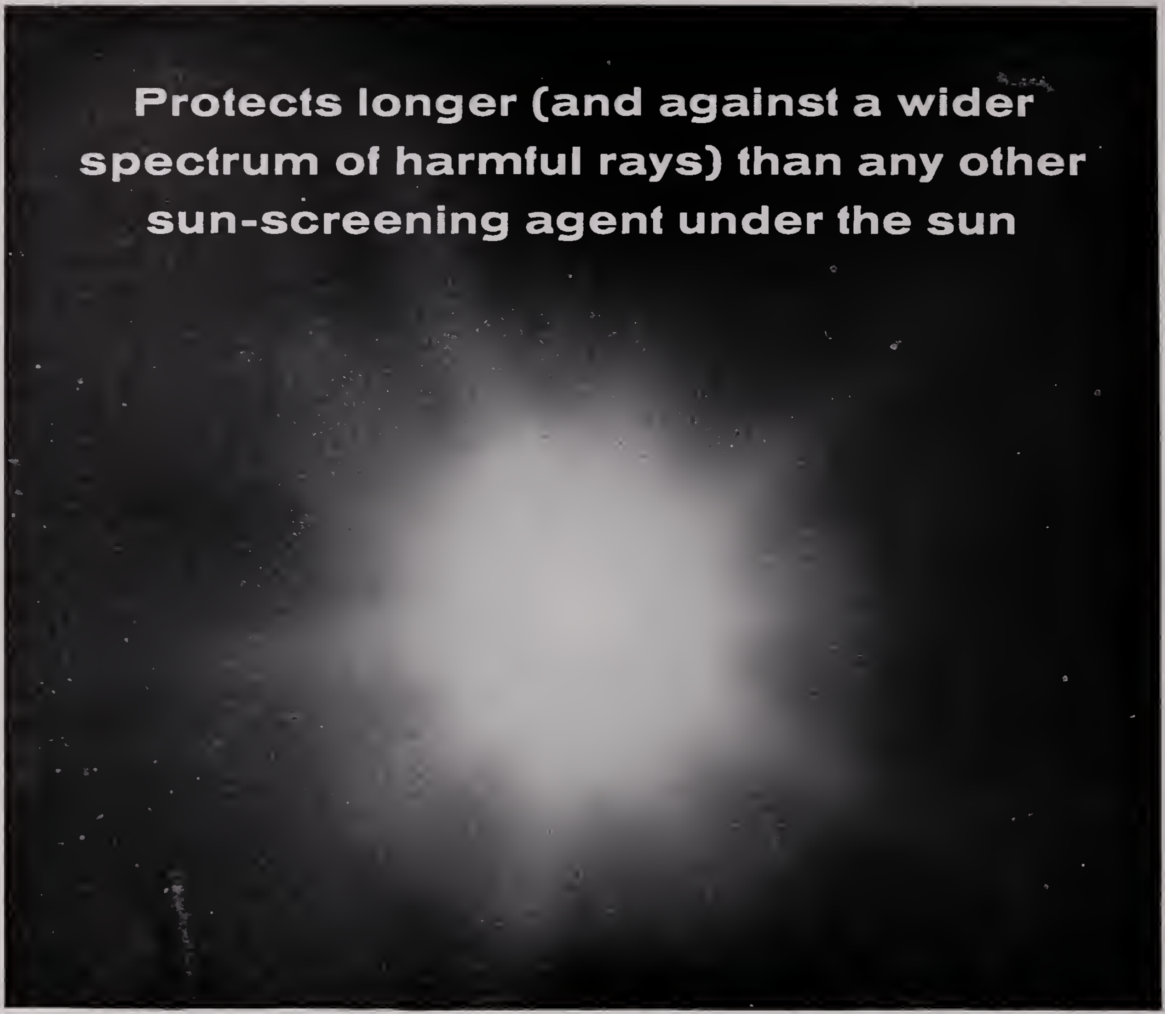
Letter to the Editor:

To the Editor: Having noted your comment in the April issue of Minnesota Medicine on the "almost unlimited potential resources of the sea to provide for Earth's exploding population," I would like to counter by asking: Granted that the ocean could provide adequate food for our over-spawned masses, *who wants to eat standing up!* — E.R.



Protects longer (and against a wider
spectrum of harmful rays) than any other
sun-screening agent under the sun

new UVAL

ULTRA-VIOLET ABSORBING LOTION*

Clinical studies show that many drug-induced photosensitivities are initiated by solar rays longer than 3200 Å. Most commercial lotions absorb *only short, burning rays up to about 3100 Å.* New UVAL provides excellent screening of short, erythema-causing waves *and* sustains high effectiveness throughout the photosensitizing spectrum (up to 6500 Å). Moreover, laboratory studies in humans demonstrate that UVAL protects *hours longer*‡ than any other sun-screening agent available. Such protection is unprecedented. UVAL has no known contraindications and is cosmetically acceptable. Literature (including a list of photosensitizing agents) and samples available on request.

‡As long as UVAL remains on the skin

Precancerous Dermatoses

CANCER EDUCATION campaigns being carried out in this country are increasing the number of patients consulting physicians for various tumors or tumor-like lesions arising on the skin. With aging, the number and variety of such tumors increase. Fortunately the overwhelming majority of skin tumors are benign. Most of them are so characteristic as to enable the physician to make an accurate diagnosis on inspection alone. In others histopathologic examination is needed. The sooner an opinion can be given the greater the opportunity of curing the lesion if it is actually malignant.

The premalignant or precancerous lesions, discussed in the June issue of MINNESOTA MEDICINE* as a broad group are often seen and usually easily recognized. The most common and important lesion in this group is the actinic or senile keratosis. Recent inroads have been made regarding the etiologic factors playing a role in the premalignant lesions of the skin. A variety of biological, physical, and chemical factors have been studied experimentally in animals and have provided substantial support for the opinion that these factors are also operative in human skin cancers. The so-called biological factors are: inherited susceptibility, skin color, sex, specific sites and age. The important physical factors are mechanical trauma, burns, actinic radiation or ultraviolet light, ionizing radiation from X-ray sources, radium radioisotopes, and cosmic rays. Among the chemical factors which have been shown to cause precancerous and cancerous lesions of human skin are materials contained in or derived from petroleum, coal, shale and compounds of arsenic.

Probably the most important etiologic factor today is sunlight. This is exemplified in many studies showing the low rate of skin cancer in the negro as compared to the white population. Significantly, cutaneous cancer is much more common in the southern than in the northern latitudes. An examination of cancer rates for all organs reveals that only in the case of skin cancer is there a clear-cut difference on the basis of geographic location, the rate being greater in the south than in the north. A recent survey in Honolulu demonstrates that skin cancer is 45 times as common among Caucasians as among non-Caucasians and over 90 per cent of skin cancers are found on the exposed areas such as the face, neck, hands and forearms. Further evidence of the etiologic importance of solar radiation is demonstrated in outdoor workers who have a much higher incidence of skin cancer than those working indoors. It has also been shown that ultraviolet radiation induces cancer of the skin in mice and rats.

Prevention of precancerous and cancerous lesions means essentially the avoidance or removal of those factors which may influence the development of these lesions. It may be advisable to acquaint young individuals who have outdoor occupations with the consequences of long-term sunlight exposure. This is particularly important for individuals with blue eyes and fair complexions. An effective sunscreen preparation such as 15% para-aminobenzoic-acid ointment, which screens out rays in the range of 2800 to 3100 Angstroms can be prescribed when sun exposure is unavoidable. When early changes are visible, recreational sun exposure and the use of photosensitizing drugs or substances should be curtailed. Patients showing these precancerous lesions should be advised to have periodic medical examinations. Any lesion showing suspicious changes should be biopsied as should all new lesions suspected of being potentially malignant. The prevention of cutaneous carcinomas is practical only insofar as we can recognize and eradicate such etiologic factors as chronic sunlight exposure, intermittent trauma and chemical carcinogens and adequately prevent, treat or keep under surveillance the various premalignant conditions.

to help relieve pain
in common
anorectal disorders

"non-caine"
Diothane®

Diothane—with its chemically distinct "non-caine" anesthetic agent diperodon—provides effective temporary topical anesthetic and emollient actions for soothing relief of anorectal pain. Anesthetic activity is effective and relatively prolonged; sensitization is infrequent. Reports to Merrell on 1,500 patients treated pre- and postoperatively with Diothane Ointment, indicate only 22 developed local skin reactions. Reactions to Diothane have been burning or stinging sensations and a few cases of allergic manifestations. An additional advantage: Diothane Ointment and Suppositories are mildly antiseptic. Prescribe or recommend either form...both are now available.

DIOTHANE OINTMENT

COMPOSITION:
diperodon 1.0%; oxyquinoline benzoate 0.1% in a special ointment base.

INDICATIONS:
Provides temporary palliation of pain that may result from hemorrhoidectomy and from common anorectal disorders such as hemorrhoids, anal fissures, pruritus ani.

DIOTHANE® OINTMENT
CHILL
PULL APART

DIOTHANE SUPPOSITORIES

COMPOSITION:
Each suppository, weighing approximately 2.6 Gm., contains diperodon 1.0%; urea 10.0%; oxyquinoline benzoate 0.1% in a special hydrophilic suppository base. A unique shape keeps the suppository in intimate contact with mucous membranes.

INDICATIONS:
Provide for temporary palliation of pain caused by hemorrhoids and pruritus ani.

Laboratory Standards in Minnesota Hospitals

THAT "TROUBLE IS NORMAL," is a Dr. Gerald Evans' axiom which is firmly drilled into the skulls of clinical pathology residents, those peculiar animals usually found roaming semiconsciously through that forest of threatening machines, graphs, complex glassware, chemicals, slide rules, variously assorted body "specimens," ringing telephones, coffee, and gorgeous girls, the conglomerate of which is called a clinical laboratory. As a matter of fact, one might say that the excellency of a clinical laboratory is directly proportional to its ability to discover and correct its errors.

In this issue of Minnesota Medicine* is a report of a two-year study of clinical chemistry determinations in Minnesota hospitals conducted by the Minnesota State Department of Health. This study was more than a mere survey of laboratory performance, however. It is one thing to show a laboratory that it has erred and quite another to correct the errors. As was true of many other past surveys, the present survey did indeed show that clinical laboratories are having troubles. But the intent of the present study was much greater than just to point out laboratory difficulties. Its major purpose was to see whether a series of performance surveys interspersed with technical consultations could improve the quality of hospital laboratory performance in clinical chemistry.

One hundred and ten hospitals voluntarily participated in the study. Over two hundred hospitals were invited to participate. The larger the hospital-bed capacity, the greater was the percentage of participation. For example, 94.1% of the invited hospitals with over 250-beds took part; whereas only 32.6% of the hospitals invited under 25-beds participated. The same relationship held true of those completing the study. One hundred per cent of the over 250-bed hospitals group completed the study, whereas only 62.5% of the under 25-bed hospitals group completed the study.

Eighteen separate surveys were conducted over a period of 22 months. The surveys were divided into three phases. Phase I, a preconsultation phase, was used to establish a base line of performance and divide the laboratories into three groups. The best performing one third of the hospital laboratories was called the criterion group. This group received no other help except that they were notified of the results of one survey before the next survey specimens were mailed. The remaining two thirds were divided randomly into a control group and a consultation group. The control group represented a group whose results were similar to the consultation group in Phase I but whose improvement (if any) in Phases II and III would be from self help only. Each hospital in the consultation group received at least three visits from a consultant clinical chemist during Phase II. Chemistry workshops attended by at least one member from each consultation group hospital were also held. Phase III was a post-consultation survey. The survey specimens to be determined were glucose, calcium, chloride, hemoglobin, urea nitrogen, total protein, uric acid, and cholesterol. The hospitals needed to do only those tests which were routinely done in their labs. The labs also completed questionnaires regarding the level of training of their personnel, administration, type of equipment, supplies, etc.

The results of the study are not too surprising. The best performing labs were those which had the best trained personnel and supervision, i.e., the greatest number of American Society of Clinical Pathology registered technologists (or equivalent), and supervision by pathologists. In general, these were also the hospitals with the largest bed capacities and the heaviest work loads. Furthermore, the best performing labs in Phase I also showed the greatest improvement in Phases II and III. Well-trained personnel were able to improve through participation in evaluation studies alone. This was not true for less well trained personnel who did not improve by mere participation in an evaluation study.

As far as consultation is concerned, a clear-cut effect was noted only in one determination. There was a significant improvement in

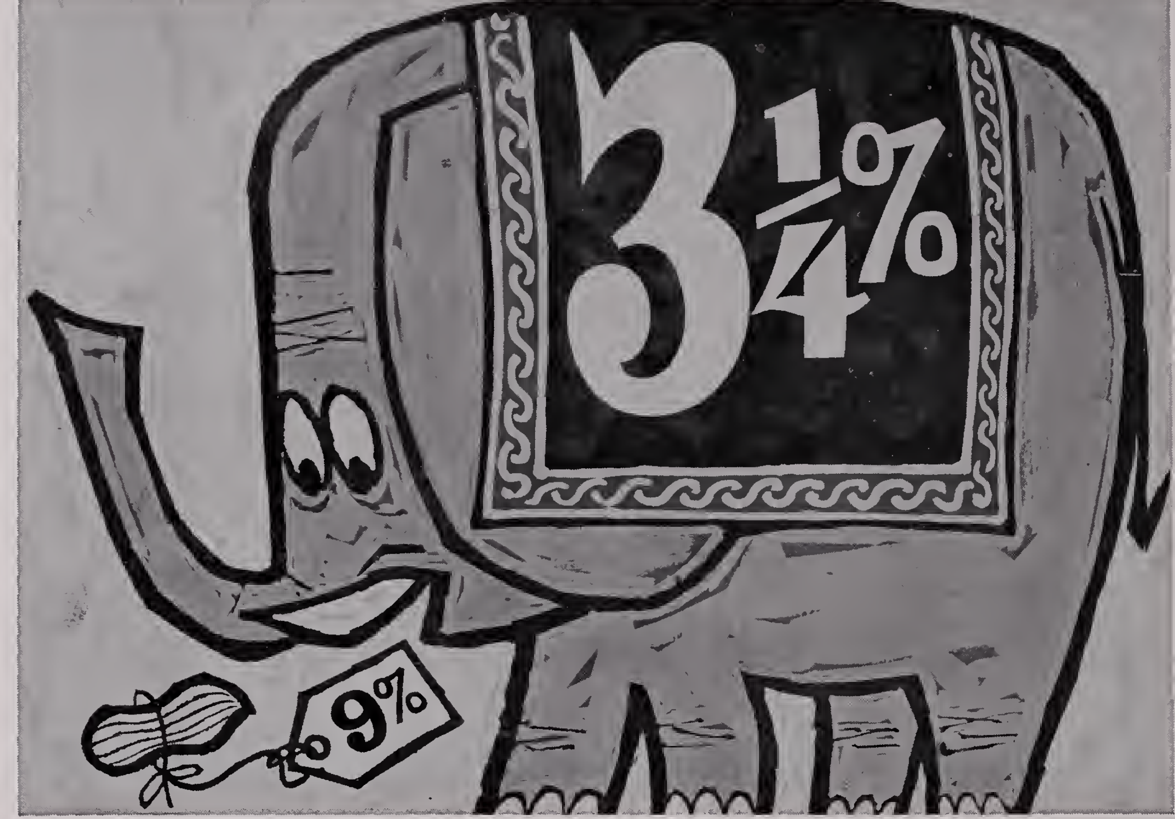
Riddle:
When is 3¼% larger than 9%?



Answer! When it represents *keepable* income from tax-free municipal bonds! A 9% yield from ordinary stocks may seem like a nice profit. But, it's really small peanuts, if you're in a high income bracket. Reason? Federal and state income taxes can take a huge amount of that profit away. Not so with *tax-free* municipal bonds! They allow you more "keepable" income . . . more big peanuts to salt away in your trunk! First National Bank offers a large selection of these bonds. Sound good? Then mail the coupon below for our free booklet "The Story Behind Municipal Bonds," as well as our handy "Tax Exempt Versus Taxable Income Table." Both give you vital information that can save you money. Or call our Investment Department (221-9463). So make like an elephant—don't forget—tax-free bonds can give you more *keepable* income!

hemoglobin determination in the consultation group in both accuracy and precision, and the control group did not show this improvement. The only other significant net change was for the serum calcium determination which actually showed a deterioration in accuracy.

The need for better trained personnel and constant supervision by qualified physicians, especially in "smaller" hospital laboratories, is evident. Occasional consultations will not suffice. The stimulus for improvement in laboratory performance should come from the practising physicians. That some physicians are lax in demands on their labs is evident from the number still using total reducing substance methods for reporting blood sugars instead of true glucose methods. It behooves all clinicians to study the article by Merritt, et al. in this issue of Minnesota Medicine.

The ideal hospital laboratory would have adequate numbers of well-trained ASCP technologists; American Board certified clinical pathologists; daily quality control programs to determine reproducibility of results; outside standards, surveys and check specimens to determine accuracy; calibration of laboratory equipment such as photometers, cuvettes, and quantitative glassware; and finally, approval of the laboratory by the American College of Pathologists inspection program. Even under these theoretically ideal conditions errors are still frequent. These are individual errors which are difficult to control and are of great variety. Clerical recording errors, transposition of colorimeter readings, misplaced decimal points, unnoticed scratched cuvettes, unnoticed chipped pipette tips, stasis of blood in drawing, drawing while I. V. running, physiologic stress phenomena not taken into consideration, using the wrong pipette, and medications that interfere with methodology or prejudice the results are only a few examples of such errors. The laboratory depends upon the astute practising physician to help control these individual errors. Clinical lack of correlation with laboratory results should be reported to the lab immediately. A happy, relaxed, laboratory atmosphere with good morale is also important in keeping individual errors at a minimum. The physician can do much for laboratory morale and actually improve the laboratory services given to him, by not abusing "stat" and "emergency" lab requests and by vocalizing his lab criticisms directly to those in charge of the laboratory in a constructive and friendly manner. "To err is human; to forgive divine."

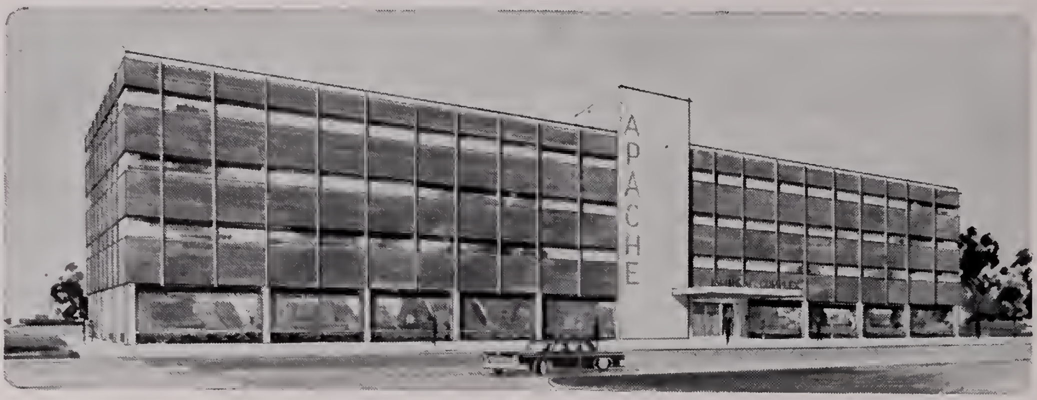
Community Service Conference on Neurological Disorders

The University of Minnesota Medical Center under the Comprehensive Clinic Program, is now engaged in a project designed to enhance service to patients with neurologic disease through greater community-university cooperative participation. As a part of this program, weekly or bi-weekly conferences are held at the University in which the referring physician participates along with the neurologist, psychologist, and other consultative community and university personnel who have seen the patient. Publication of selected conferences are published in "Minnesota Medicine" as a part of this project.

Inasmuch as women are always willing and able to explain their strong points, they leave us to guess at their weak ones. — Balzac

We all have weaknesses. But I have figured that others have put up with mine so tolerably that I would be much less than fair not to make a reasonable discount for theirs. — William Allen White



You've Made Us Change

APACHE MEDICAL COMPLEX

We started with plans for the most modern, most efficient, most tenant-oriented *medium-sized* medical complex in Minnesota. Your response forced us to change our plans. Now we're going to construct the most modern, most efficient, most tenant-oriented *large-sized* medical complex in Minnesota, to be built at Apache Plaza in two medium-sized stages. Stage 1, pictured above, will be ready for you in Spring, 1966.

Here are some of the reasons why Apache Medical Complex will be the ideal location for your new office:

Coetaneous — contemporary (page below).

Beau monde — literally, beautiful world; by extension, worldly society (page below).

The Editor's Soliloquy

Utopia*

Utopia? — It is an ego-oriented society where everyone is free from illness, burdens, responsibilities, anxieties, apprehensions, worries; where the goods of life are available for the asking, where every man can have his cake and eat it, too, but no one need bake it; where rights and special privileges prevail without corresponding duties or onerous obligations, where a self-supporting government provides everything and demands nothing in return.

It is a society where the slogan "The Lord will provide" has been superceded by the expediency of "The Government will provide" without any *quid pro quo*; where the Jeffersonian ideal of independence has been abrogated in favor of parasitism. The paradox is obvious: as an individualistic society becomes more affluent, its humanitarianism impels it to ameliorate, if not eliminate inherent economic inequalities — only to discover too late that it has unwittingly fostered a bastard ideology of dependency.

Thomas More who coined the term, was not the only one who envisioned a nobler society. There were other Utopias: Plato's Republic, Augustine's City of God, Bacon's New Atlantis, and Campanella's City of the Sun: where only the virtues of human society prevailed; where there was no occasion to condemn, to blame, to censure; and where no vice existed — the nebulous felicity that always seems to pre-exist the coetaneous,* corrupt *beau monde.**

"All Registered Nurses are Alike"

It stands to reason. They all go through the same training; they all have to pass the same tests: they all have to measure up to the same standards. Therefore, all registered nurses are alike.

That's nonsense, of course. But it's no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more demanding. In fact, there are at least *nine specific differences* involving purity, potency and speed of tablet disintegration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn't so.

You might also say that all registered nurses aren't alike, either.

Percutaneous Transhepatic Cholangiography

QUESTION: How often would you recommend transhepatic cholangiography in preference to cholangiography at the time of exploration or laporatomy?

ANSWER: The patient with what appears to be complete extrahepatic biliary obstruction constitutes a diagnostic problem. Percutaneous transhepatic cholangiography provides information that enables one to proceed rather directly with a definitive procedure. It has been particularly helpful to us in patients with stricture of the common duct, carcinoma of the ampulla of Vater, and cancer of the pancreas. If we really believed that the patient had a common duct stone, it is likely that we would not do a percutaneous approach, but do a cholangiogram at the operating table.

One of the great advantages of the percutaneous method is that it is done in the X-ray department with the many facilities that we do not have in the operating room. These include films taken from any angle, and cineradiography of the procedure. Also, we are sometimes able to demonstrate the dye entering either vascular or lymphatic channels.

Frank Glenn, M.D.
Cornell University Medical College

Spinal Cord Injury

QUESTION: I have recently witnessed the tragic consequences of spinal cord injury following aortography. Is there any way this complication can be avoided?

ANSWER: The following safeguards are suggested:

1. The contrast agent selected should exhibit the least nephro- and neurotoxicity. Currently 50-90% Hypaque is recommended.
2. The instillation of contrast material should be limited to a single injection.
3. If possible, the study should be carried out in the prone position.
4. The smallest volume of contrast material should be used commensurate with adequate visualization of the area being studied.
5. Some workers have suggested that barbiturate anesthesia should be avoided.

It is foolish to pluck out one's hair for sorrow, as if grief could be assuaged by baldness. — Bion

the problem: diabetic and overweight...unresponsive to diet alone

the answer: In the regulation of the diabetes "...if dietary control seems to be unsatisfactory...[and] if the patient is overweight...our first choice is phenformin [DBI], since this is the only oral hypoglycemic agent commercially available at present which does not promote fat deposit."[1]

"...with phenformin [DBI] there may be less preferential stimulation of fat synthesis in the obese, diet-resistant diabetic, favoring both blood sugar and body weight control."[2]

to manage the stable adult diabetic who is overweight and unresponsive to diet alone

DBI®-TD brand of **PHENFORMIN HCl**

timed-disintegration capsules 50 mg.

DBI together with a proper diet usually affords effective control in the overweight ketoacidosis-resistant diabetic...reduces high blood sugar and elevated serum insulin levels, thus leading to gradual weight loss.[3] Anorexia has been suggested as a possible basis for weight loss. However, controlled studies suggest that it is due to the mechanism of drug action. Comparable dosages of DBI do not induce weight loss or lower blood sugar in non-diabetic subjects. For the ketoacidosis-prone diabetic, insulin is still the essential hypoglycemic drug.

Dosage: 1 to 3 capsules daily. **Side Effects:** Gastrointestinal, occurring more often at higher dosage levels, abate promptly upon dosage reduction or temporary withdrawal. **Precautions:** Occasionally an insulin-dependent patient will show "starvation" ketosis (acetonuria without hyperglycemia) which must be differentiated from "insulin-lack" ketosis which is accompanied by acidosis, and treated accordingly. Lactic acidosis has been reported in nondiabetics and diabetics treated with insulin, with diet, and with DBI. Question has arisen regarding possible contribution of DBI to lactic acidosis in patients with renal impairment and azotemia and also those with severe hypotension secondary to myocardial or bowel infarction. Periodic B. U. N. determinations should be made when DBI is administered in the presence of chronic renal disease. DBI should not be used when there is significant azotemia. Any cardiovascular lesion that could result in severe or sustained hypotension, which may itself lead to development of lactic acidosis, should be considered cause for immediate discontinuation of DBI at least until normal blood pressure has been restored and is maintained without vasopressors. Should lactic acidosis occur from any cause, vigorous attempts should be made to correct circulatory collapse, tissue hypoxia, and pH. **Contraindications:** Severe hepatic disease, renal disease with uremia, cardiovascular collapse. Not recommended without insulin in acute complications of diabetes (metabolic acidosis, coma, severe infections, gangrene, surgery). **Pregnancy Warning:** *During pregnancy, until safety is proved, use of DBI, like other oral hypoglycemic drugs, is to be avoided.*

Consult product brochure. **Also available:** DBI tablets 25 mg.

Fracture–Trauma Conference

The Fatal Triad—Skull, Pelvis, Extremity Fractures

The combination of skull-pelvis-extremity fractures is particularly lethal to the patient involved in a high-speed automobile accident. It does not seem unusual that mortality and morbidity rates should rise with the number of body systems involved, but this particular combination carries with it a mortality rate that is disproportionately high. A recent review of such cases over a three-year period at the Hennepin County General Hospital revealed that only one out of four such injured patients survive their accident.

An illustrative case history of one such survivor follows:

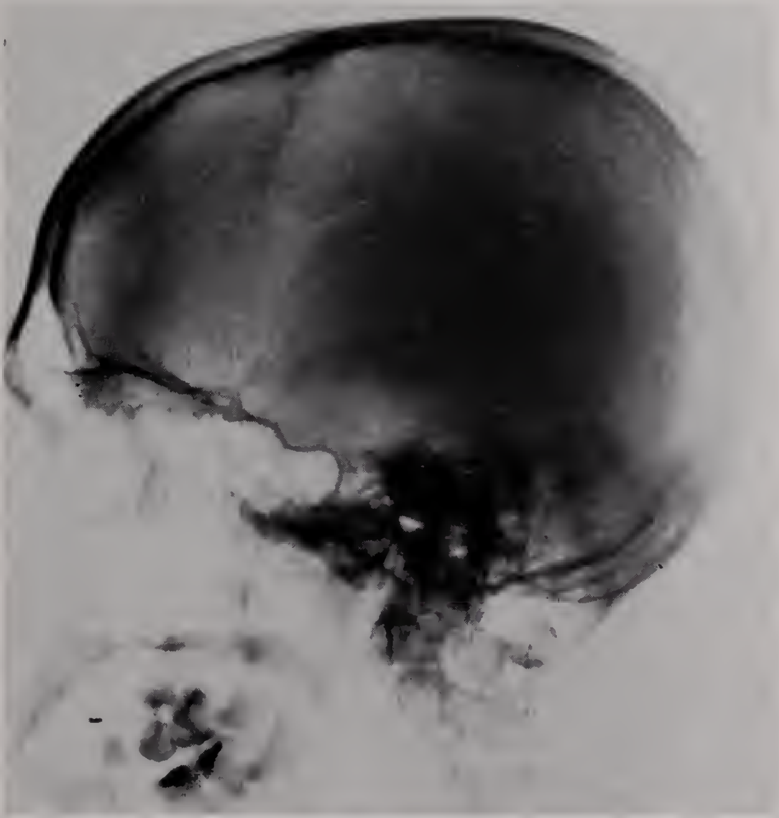

Figure 1

Continued

Case History

A 44-year-old pedestrian was struck down by an automobile and taken by ambulance to the Minneapolis General Hospital in a semicomatose condition. He was taken immediately to the emergency ward treatment room where he was evaluated.

He had an obvious head injury with a large area of swelling around the left ear and left temporal parietal area. He had also incurred a compound mid-shaft fracture of his left tibia and fibula. X-rays revealed a parieto-occipital linear nondepressed skull fracture (Figure 1), a severely comminuted left leg fracture (Figure 2), and fractures of the left superior and inferior pubic rami (Figure 3).

His initial blood pressure was 140/90, but his pulse was 116, and with a fall in the blood presure, blood replacement was started. He was disoriented, but neurological examination gave no evidence of localized intracranial hemorrhage. It was decided at this time to use a femoral sciatic regional block and treat the compound fracture. The block provided excellent anesthesia for the irrigation and debridement of the wound and insertion of a Lottes nail in the tibia. The patient remained awake during the procedure, although semistuporous, with no fall in blood pressure.

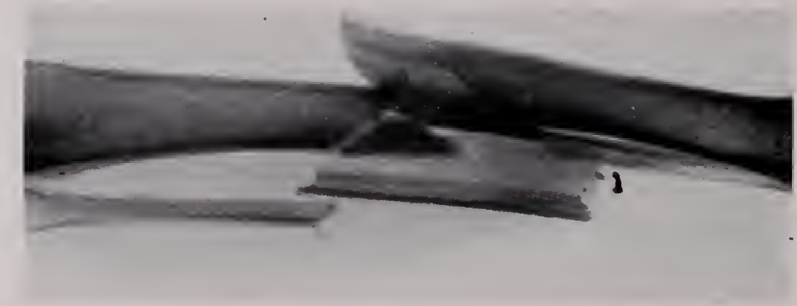

Figure 2

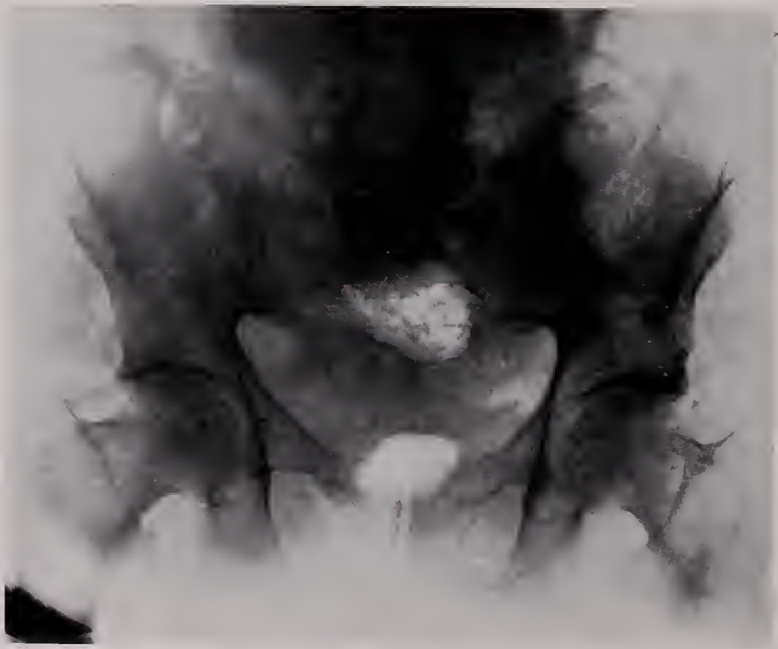

Figure 3

Postoperatively it was necessary to observe the patient closely because of an adynamic ileus, and nasogastric suction was instituted. He received seven units of blood over a three-day period until his hemoglobin had stabilized. There was no evidence of intra-abdominal organ damage. His recovery, thereafter, was rapid. His sensorium cleared and he was discharged home on the 19th post-accident day on crutches.

His last clinic visit was one and a half years later, at which time he was asymptomatic but walked with a slight limp. The fractures had all completely healed in satisfactory position.

Discussion

The physician who has the over-all responsibility for the care of such a patient must assume a heavy burden, for not only must he diagnose the separate injuries and see that they are properly treated, but he must determine the order of importance in terms of timing in correction. Several points seem worthy of consideration in the management of this difficult problem.

First, it is not uncommon that hypotension be present on the basis of retroperitoneal (hidden) hemorrhage resulting from the pelvis fracture. It is also not uncommon for the patient to be comatose from the head injury. A cause and effect relationship between the coma and the hypotension may lead to a false conclusion; if so, the patient may well exsanguinate without the proper blood replacement. This is a well documented fallacy but merits repeating.

Second, extremity fractures should be promptly splinted to prevent shock from pain and blood loss. However, definitive care can then be delayed, if the fracture is closed, until the patient's general condition has stabilized.

Third, if the extremity fracture is open or compounded, regional anesthesia may provide a good alternative to either a general anesthetic which causes added risk in the semicomatose patient or a spinal anesthetic in the patient who has only a partially compensated blood volume.

Fourth, should the neurosurgical consultant feel that there is reason for craniotomy, simultaneous definitive treatment of the extremity injury can frequently be accomplished with a consequent reduction in anesthetic time.

Summary

A case representing a favorable outcome from the frequently lethal combination of skull, pelvis, extremity fractures is presented. Experience with such cases had led to its being referred to as *The Fatal Triad.*

Harrison H. Farley, M.D.
Minneapolis, Minnesota

KLINEFELTER'S SYNDROME

The features of this syndrome include gynecomastia, small testes, aspermatogenesis without A-Leydigism and an increase in the excretion of follicle stimulating hormone. There is an increase in the follicle stimulating hormone comparable to castrates and a low normal level of 17-ketosteroids and estrogens.

If the disease starts in the prepuberal period, the typicals are a syndrome, but if it starts in the midpuberal period, it may be incomplete, though aspermia and sterility are always evident and varying degrees of eunuchoidism may be evident. Klinefelter's syndrome shows chromosome anomalies of the sex chromosomes. Any individual having immature or questionable genitalia should have a sex chromosome study, and if the clinical sex and the genetic sex are in confusion, chromosome studies should be done. — Robert H. Durham, M.D., Encyclopedia of Medical Syndromes, Paul B. Hoeber.

Paleopathology*

Paleopathology is that branch of physical science that deals with the antiquity of disease as revealed in the fossilized forms or the preserved remains of ancient organisms.

Fossils, however, supply data on only those diseases which leave their pathological record on the bones. Since tissues seldom become fossilized, the paleopathologist must remain largely ignorant of the majority of ancient diseases affecting the soft parts of the body.

There were doubtless epidemics among prehistoric animal species and early human societies that wiped out total groups; but as yet the relatively new science of paleopathology has accumulated no evidence of such fatal scourges. Future improved methods and techniques, however, may open hitherto closed doors to the archaic past to provide us with truer perspective on the evolutionary sequence and perpetuation of disease.

Fossil reptiles thus far studied give abundant evidence of five groups of pathologies: (1) arthridites (spondylitis deformans, multiple arthritis, and arthritis deformans); (2) tumors (osteoma and hemangioma); (3) necroses and caries; (4) hyperostoses (alveolar osteitis, exostoses, osseous hyperplasia, and osteoperiostitis); and (5) fractures (skull, oblique, simple, and caudal).

How did these various pathologies occur? The origin of fractures and some other injuries can be readily surmised; perhaps a rock fell on an animal or he was wounded in a struggle with another animal. The etiology of other skeletal pathologies, however, is more obscure; whether they were bacterial or tuberculous in nature has not been determined.

Had you been an ancient reptile with a well-and-smoothly-healed fracture, your good fortune could doubtless have been ascribed to two factors: first, your bones were solid, and second, your instinct of self-preservation impelled you to rest in an almost immobile position while you were recuperating — a therapeutic measure possible for you as a reptile, since you could survive for long periods without bestirring yourself to seek sustenance.

But since you possess neither armor nor a tail, your primate status would preclude a sufficient stretch of your imagination to identify with an ancient glyptodont** afflicted with necrosis of his bony armor due to the bite of a saber-toothed tiger, or with a dinosaur who developed a bone tumor overlapping two fractured caudal vertebrae.

On the other hand, you might easily identify with a Permian reptile whose infected spinal fracture resulted in osteomyelitis; or with a primitive mammal whose fractured elbow joint became ankylosed; or with a mosasaur† suffering from multiple arthritis in all joints of one hallux; or with a dinosaur whose oblique humerous fracture developed a subperiosteal abscess that permanently elevated his periosteum.

The animal pathologies described above were observed, photographed, and interpreted by Roy Moodie, Anatomy Professor at the University of Illinois, in his "The Antiquity of Disease," University of Chicago Science Series, 1923.

Tumor Conference

Cystadenoma of the Pancreas

Cystadenomas of the pancreas are unusual benign neoplastic cysts. Approximately 100 cases have been reported in the literature.[8] In 1962 Piper, ReMine and Priestly of the Mayo Clinic reviewed the literature and reported an additional 20 cases.[7] Lichenstein in 1934 and Byrd in 1956 reported malignant degeneration in benign cystadenomas.[4,5]

These lesions are usually found in middle-aged females. They may occur in any portion of the pancreas but are generally in the body and tail. They may vary greatly in size when discovered; tumors varying in size from 2 x 2½ cm. to 34 x 20 x 20 cm. have been reported. Pseudocysts, however, are usually larger than cystadenomas.

Etiology

Numerous theories of etiology have been reported. Glenner and Mallory concluded that cystadenomas originate from proliferating pancreatic duct epithelium.[1]

Gross

The tumors are embedded and often replace pancreatic tissue. They have a profuse blood supply with large blood vessels coursing over the surface. They are firm and nodular, grossly appearing as a cluster of grapes, and on section resembling a honeycomb. There is no communication between the cysts or with the main pancreatic duct. The cysts contain a viscid, mucoid, gelatinous or clear serous fluid.

Microscopic

The cysts are lined by a single layer of epithelium. The cytoplasm is clear, the nucleus basal. The cells may be flat, cuboid or columnar. The fibrous stroma between the cells may contain calcium or show evidence of hyaline degeneration. The surrounding pancreatic tissue may be normal or show evidence of compression.

Symptoms

The symptoms are those of a slow-growing lesion. In most instances the

Continued

only symptom may be that of a palpable abdominal mass. Occasionally, a patient may complain of fullness, or a sensation of pressure when bending over. There may be anorexia, constipation, or nausea and vomiting. The tumor may be found during abdominal exploration during other abdominal surgical procedures. Diabetes co-exists in 10 to 14% of reported cases; but diabetes has not been reported as a complication following surgery.[6]

Findings

A firm, round, nodular, nontender upper abdominal mass is the usual clinical finding. If the lesion is in the tail it may move with respiration. There is no movement if it is in the head of the pancreas. On roentgenography, an anterior abdominal mass may be seen, with evidence of extrinsic lesion pressing on the stomach or colon. Scout films and pyelograms help make the differential diagnosis. Calcific deposits have been noted on 15-20% of these cysts.[2]

Diagnosis

Clinical, radiographic and laboratory findings may not be specific enough for a definite diagnosis to be made preoperatively; but the existence of a relatively asymptomatic solid upper abdominal tumor in a middle-aged female should suggest the diagnosis.

Treatment

Surgical extirpation of the tumor is indicated. Marsupilization or internal drainage is not effectual, as the cysts do not communicate.

The tumor is approached through the gastrocolic omentum. Usually a

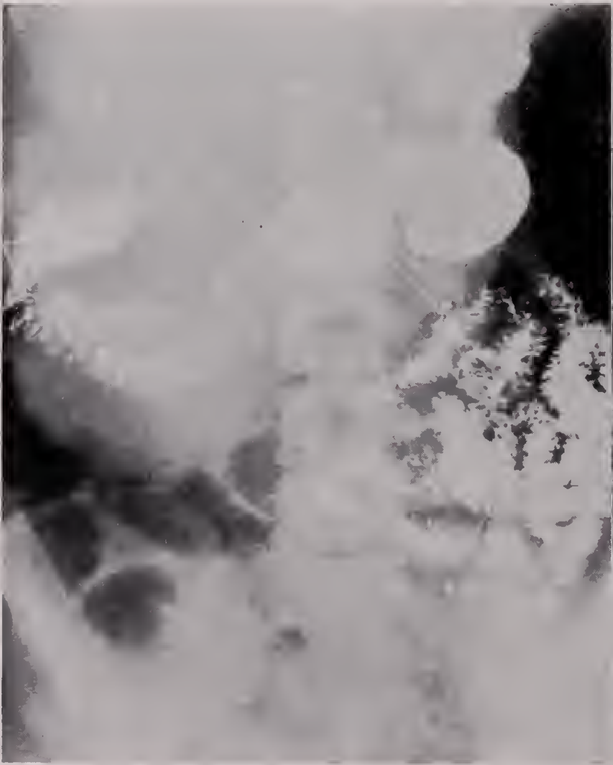

Fig. 1 — Displacement of the stomach and widening of the duodenal loop, with downward displacement of the gas-filled colon due to the tumor.

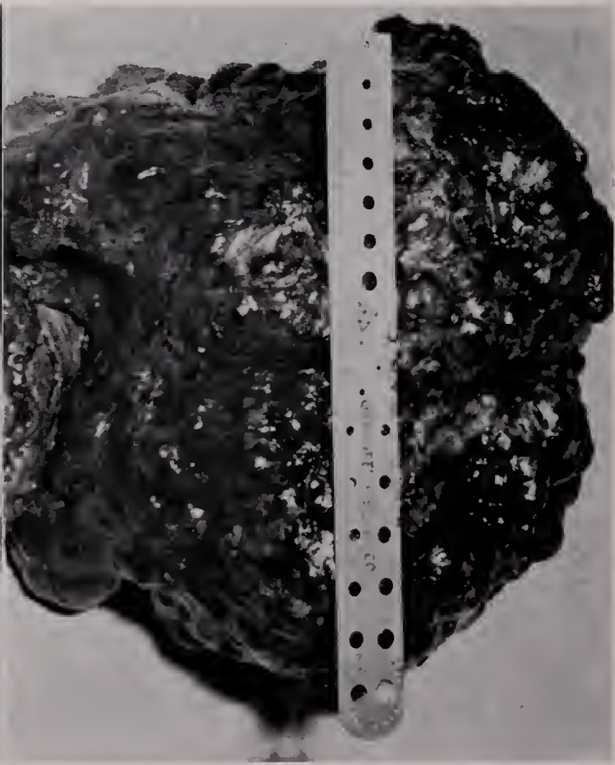

Fig. 2 — The gross specimen showing multiple cysts.

good cleavage plane can be found; but the cyst may be covered with a thin layer of pancreatic tissue. Most of the tumors are in the body and tail; if in the tail, the spleen is removed with the tail of the pancreas. Care must be taken to avoid the superior mesenteric vessels and the portal vein. If the cyst is in the head, as much pancreas as possible is preserved; and particular attention must be paid to the pancreatic and bile ducts. The preservation of even a small amount of pancreatic tissue prevents the development of postoperative diabetes. Howard believes the operative mortality rate should not exceed 2-5%.[6]

Case Report

A 54-year-old woman had consulted her physician ten years previously for a nontender upper abdominal mass. This was thought to involve the upper pole of the kidney, and she was explored through a right subcostal incision. At surgery the mass was found to be a multicystic lesion involving the pancreas. It was felt, after consultation, that removal of the mass through the renal incision would be unwise, and the wound was closed. Following surgery the nature of the lesion was explained to the patient, and removal through a transabdominal incision was advised. The patient, however, declined further surgery at that time.

She had few symptoms and continued to postpone surgery. In February of 1963 she noted a mucous discharge from the rectum. A carcinoma of the rectum 15 centimeters above the anal verge was found on sigmoidoscopy. A massive hemorrhage followed proctoscopic biopsy. After transfusion, an anterior resection of the rectosigmoid was done. The upper abdomen was explored at the time of surgery and a large, multilocular cyst occupying the major portion of the upper abdomen was found. The duodenum was stretched over the mass. The pancreatic lesion was not disturbed. Following the bowel resection a fecal fistula developed, and a temporary colostomy was done. The colostomy was closed six weeks later.

The patient did well postoperatively but began to have abdominal discomfort after meals.

One year later, after careful clinical and roentgenographic examination revealed no evidence of recurrence of the rectal carcinoma, she was ad-

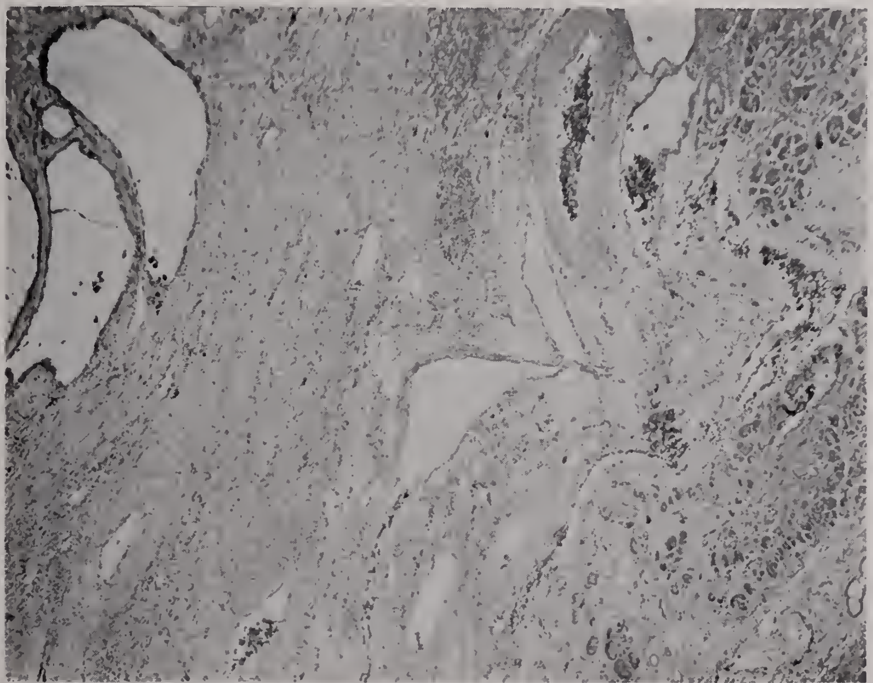

Fig. 3 — Microscopic section showing the dense fibrous stroma with trabeculations and cystic areas.

Continued

mitted for surgical removal of the pancreatic cyst. A right and left subcostal incision was made. The gastrocolic omentum was taken down, exposing the body and tail of the pancreas. The very large tumor was apparently confined to the head and uncinate process of the pancreas, as there was no tumor to the left of the mesenteric vessels. The vessels were pushed to the left and the duodenum to the right, as the tumor measured 20 cm. x 14 cm. x 9 cm. The common duct was transected above the tumor, and 10 centimeters of the second portion of the duodenum resected with the cystadenoma. There was no identifiable duct system left in the small, atrophic-appearing tail of the pancreas. The common duct was anastomosed to the duodenum and the duodenum reapproximated, with a T-tube in the common duct, one limb extending thru the choledochoduodenostomy. Penrose drains were placed in the area of resection and the abdomen closed.

On gross examination of the tumor numerous cysts of various sizes were seen protruding from the surface. The cysts had a smooth inner lining and contained a thin clear, or serosanguinous fluid. No papillary tumor was found. Throughout the specimen, areas of fibrosis and even calcification were found. The pancreatic tissue could be identified.

On microscopic examination the stroma was found to be a dense fibrous tissue, which resembled scar tissue and formed an intricate pattern of trabeculations that varied in thickness and density. A few of the cysts lacked an epithelial lining, but the majority were lined with a single layer of cuboid epithelial cells. There was no evidence of epithelial activity.

A few areas of pancreatic tissue were found; in some areas the pancreatic tissue was considerably compressed. The islets of Langerhans appeared to be normal.

On the first postoperative day the patient had glycosurea and a blood sugar of 157 mg. per 100 cc. of blood. On the following day there was no glucosurea, and her blood sugar remained normal. Her convalescense was uneventful; she was discharged from the hospital on the fifteenth postoperative day. Her T-tube was removed four months later.

She has continued to do well, has maintained her weight, and has shown no glucosurea. Her fasting blood sugar analysis has been reported within normal range.

Summary

A case of large benign cystadenoma known to exist for 10 years of the pancreas is reported. It was surgically excised, with a small amount of pancreas preserved. Postoperative diabetes did not develop.

Phenylketonuria*

Seven-Year-Old Female Presenting with a School Learning Problem and Incoordination

Dr. David Piepgras:**

This seven-and-one-half-year-old white female was referred to University of Minnesota Hospitals by Dr. Paul Meyer of Faribault, with the possibility of muscular dystrophy. The mother felt that the patient's problem was primarily "stiffness on getting up in the morning, incoordination at play, and holding her pencil funny."

The child is the product of a full-term normal delivery, weighing six pounds, seven ounces at birth. Her development shows that she held her head up at one month, rolled over at three to four months, sat at five and one-half months, walked at 15 months, and said single words at 12 months. The mother states that her development was slow compared to that of her other children.

Approximately one year ago the mother observed that the child had a "coordination problem" when she became overly tired. In school it was noted that she had a short attention span and trouble with writing; her words ran together and her letters were of varying sizes. However, her school performance had previously appeared to be quite satisfactory. In the preceding six months her teacher had remarked that the patient ran "funny" and had apparent trouble in starting to run, as she appeared "stiff-legged." It was also noted that her "legs are stiff in the morning and she has trouble descending stairs and holding things in her hands," especially her fork and her pencil. These symptoms are more noticeable when she is tired and are not associated with weakness.

The review of symptoms shows that she had severe eczema from two months to two years of age and is allergic to penicillin. She has had no convulsions, irritability, excessive vomiting or other neurological symptoms.

---

*See Phenylketonuria in Minnesota: Minnesota Med 47:501, 1964.

Sponsored by the U. S. Public Health Service Grant N2502A63. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals. The pediatrics conferences are held the first and third Wednesdays of every month from 1:00 to 2:00 p.m. The adult conferences are held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Robert W. ten Bensel, in Pediatrics, and Dr. Robert Soll, in Adult Neurology.

Conference held on January 6, 1965.

**Senior Medical Student, University of Minnesota.

Continued

The mother is 35 years of age and the father 32. The parents were divorced four years ago and the patient is the only child by this marriage. The mother has two children by a subsequent marriage, who are both apparently normal. The paternal grandfather died of "muscular dystrophy" at age 50. There is no other documented history of neurologic disease in the family.

The patient lives with her mother, step-father and two step-sisters. The family group interaction is not well known as the mother rarely talks about the family, even on direct questioning.

Physical examination shows an obese (94-pound), alert and pleasant white female with brown hair and hazel eyes. Vital signs are normal. Examination of the eyes, ears, nose and throat is normal. No heart murmur is heard and no masses felt on palpation of the abdominal wall. Neurological examination shows no motor weakness and good muscular strength. Her reflexes are bilaterally equal, and there are no pathological signs. Her Romberg is negative and her gait somewhat wide-based, with her feet rotated externally; but she has a steady gait.

The initial impression was that the child may be having an adjustment reaction to family stress.

Laboratory work, including a white count, urinalysis and Mantoux, was negative with the exception of a positive ferric chloride test.

Dr. Paul Moe:*

The patient is observed to be a pleasant child, but somewhat nervous and maladroit** in her movements. Neurological examination shows normal cranial nerve function and a head size of 51.5 cm. (normal). Her reflexes are symmetrical and somewhat hyperactive. There is questionable athetoid** posturing drift of the left arm. Serum muscle enzymes, drawn because of the family history of muscular dystrophy, were all within normal limits. Another ferric chloride test was performed and was strongly positive. A blood phenylalanine level was 45 mg. per cent.

Mr. Art Straub:†

Presently the patient weighs 101 pounds and is 51 inches tall. Her incoordination, which was very evident six months ago, as manifested by her not being able to write between lines, is now diminishing. Her nervousness is also decreasing, and she is described by her teacher as "cooperative, willing, even-tempered, happy and friendly." Her work is still in the low average range, has an unorganized quality and is somewhat "messy;" but she stands sixteenth in a class of twenty-two. When given a multiple choice situation it is difficult for her to make a decision. She seems to demand and receive a great deal of attention from her teacher; directions frequently need repeating before she is able to carry out a task. She used to talk a great deal to herself; now she indulges less in this autologic** habit. A good mother-child relationship appears to be present, as the mother and patient are doing exercises in an attempt at weight reduction.

Generally, the school feels that she is producing satisfactory work and

---

*Pediatric Neurologist, University of Minnesota Hospitals.

**See Test Your Word Score Page 901.

†Principal, Lincoln Elementary School.

Continued

has a feeling of success. She is particularly interested in music and has a good voice. She does stand out in her class because of her large size and her incoordination, and this is what prompted the initial evaluation by Dr. Meyer, who subsequently referred her to the University.

Mr. Earl Schramm:*

This child will remain in a regular school class as long as this is feasible and her academic work progresses satisfactorily. Faribault has special education classes in the grade school, junior high school and senior high school. At the present time, there are two sections in the grade school, but I feel that these are not now indicated because of her satisfactory progress at the present time.

Dr. Harold Ireton:**

On psychological testing performed at the Lincoln School in March, 1963, she scored an I.Q. of 74 on a Stanford-Binet. Testing in July, 1964, at the University of Minnesota Hospitals indicated significant intellectual impairment. A measure of the verbal intelligence (Wechsler Intelligence Scale for Children) plus the child's talkativeness suggested an average intelligence (verbal I.Q., 94). However, other clinical and test evidence suggest that she may not be capable of functioning at this level. Clinically she appears highly distractible. In tests of spatial relationships and visual motor coordination, she does relatively poorly (WISC performance I.Q. 71, inferior Bender). She has exceptionally poor recall. Such a pattern of functioning suggests a brain-injured child, and her hyperactivity would predict learning difficulties in a standard school situation.

While it has been reported that she has fair success in school, a reading problem has been noted. The results of the above evaluation point to increasing difficulty in school and the need for special class education or special attention to take account of her deficits. The question must be raised as to whether the improvement she has made in the past four months is apparent or real; it could be misleading and bar her from receiving the special help she is certainly going to need.

Mr. Straub:

Her reading has improved this past year, and a reading achievement test performed in the second grade showed a score of 1.9 grades. Small class size and individual attention certainly may be a factor in her improvement.

Dr. Robert Fisch:†

We would expect no further intellectual deterioration, as children with phenylketonuria at this age remain stable. Brain damage occurs in the first two years when the brain is maturing at a rapid rate.[1]

I was told after the first visit that this patient had normal intelligence; however, a personal interview with mother and child revealed that the child had borderline low intelligence. Therefore this case is particularly interesting because of the patient's relatively high I.Q. for an untreated phenylketonuric. Phenylketonuria is quite rare, affecting 1/20,000 to

---

*Director, Elementary Education.

**Psychologist, University of Minnesota Hospitals.

†Pediatrician, Director, Phenylketonuric Clinic, University of Minnesota Hospitals.

Continued

1/10,000 children born. Only two cases have been reported with I.Q.s greater than 110, and only one per cent of the untreated patients have borderline normal intelligence.[2]

Unfortunately, we very often see that parents and even physicians overlook the slow development of children; and when school failure calls attention to the borderline brain-damaged child, the time is rather late for significant correction of the pathological condition. This patient had early, slow development by comparison with her siblings. Besides, the presence of eczema, often seen in phenylketonuria,[3] should have instigated an early diagnosis.

The implications of the diagnosis are several. First, in terms of genetic counseling to the family, early diagnosis is extremely important, since recessive inheritance is involved and there may be other children affected. The two half-siblings of the patient have been tested and found to have normal phenylalanine blood levels. Genetically, the divorce of the mother was a fortunate, preventive measure.

The question is now raised as to whether low phenylalanine diet may be of benefit to this patient. There is evidence that there may be improvement of symptoms in severely affected untreated phenylketonurics. A case illustrating this point is that of a 12-year-old boy who, after four months on the diet, showed marked improvement in his writing ability (Figures 1 and 2). One of the main factors to consider in placing an older phenylketonuric on the special diet is that the diet requires a great deal of patient parental effort because it is unpalatable and restricted. The cost is also somewhat prohibitive in some cases; for a patient six to 12 years old this usually runs from $60 to $120 a month.* On the basis of intelligence alone, Jervis[4] has stated that the diet is of no benefit after three years of age; therefore, at the present time I do not feel that diet is indicated for this child.

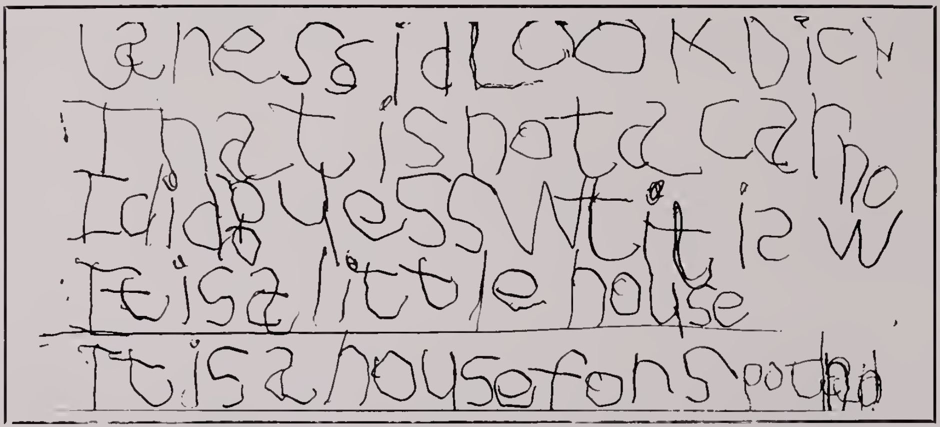

Fig. 1 — Handwriting of a 12-year-old untreated phenylketonuric child before low-phenylalanine diet.

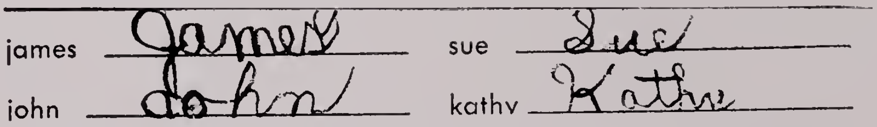

Fig. 2 — Handwriting sample after four months of low-phenylalanine diet.**

---

*The expense of the formula can be tax deductible. The expense depends upon the amount of formula needed and the different price charged through pharmacists.

**Photographs courtesy of Dr. Robert Fisch.

As this patient becomes older and approaches the child-bearing age, pregnancy would be an indication to start the diet. There is data to suggest that high phenylalanine in the mother's serum may be a cause of mental retardation. The obesity which this child shows has also been seen in some untreated phenylketonurics; the reason for this is unknown. Most of the children, however, who are on the diet, belong to the lower weight group for their age.

This family is of low economic status and it is difficult for them to keep appointments and meet obligations. For this reason, a complete evaluation has not been made, such as an electroencephalogram and skeletal survey. Hopefully, it may be possible in the future to obtain money from a research grant for further studies as they are indicated.

This patient will provide a case for observation and a standard for comparison until better testing methods are devised for psychological testing of phenylketonuric children. There is no necessity for her to return to Phenylketonuric Clinic before this summer. The school situation is certainly adequate at the present time; but the patient should have yearly psychometric examinations.

Dr. Heinz Bruhl:*

This case is indeed very interesting and points out the need to screen for phenylketonuria older children who have minor neurological abnormalities and/or school difficulties. This may lead to recognition of families in which the abnormal gene might not otherwise be discovered.[5] Knox[6] reported 20 untreated phenylketonurics with I.Q.s of over 60, and there are in the literature approximately 25 cases with I.Q.s of over 70. In Minnesota, there are a substantial number of phenylketonurics: 56 at the State Hospital in Faribault and 52 at the University of Minnesota, whom Dr. Fisch is following.

At Faribault State School we have tried the low phenylalanine diet on ten older phenylketonuria patients on a control basis for five years.[7] The diet produced favorable somatic changes, including improvement of skin conditions, decreased muscular rigidity, better coordination and motor functions. However no significant improvement in intellectual ability was produced. This study makes it imperative that phenylketonuria be diagnosed within the first few months of life before permanent and irreversible brain damage has occurred.

Final Recommendations of the Conference

1. Dr. Meyer will maintain primary medical responsibility in this case.
2. Communications will be maintained by Dr. Fisch with Dr. Meyer and the school officials regarding any recommendations about therapy or counseling.
3. The family should be encouraged to seek help from the County Welfare Board if borderline economic status precludes adequate medical care.
4. Psychometric testing should be performed at yearly intervals by the school or at the University of Minnesota Hospitals.
5. Consideration should be given to the patient as a growing child,

Surgery Comes into Its Own

The surgeon entered the new century (the Twentieth) as someting of a popular hero, a man henceforth destined to share the not-always-welcome limelight turned on him by an inquisitive press. In the popular mind his prestige had begun to outweigh that of the physician. Here was a man who had as much skill and subtlety in his fingers as a great violinist, a brain as cool and calculating as a general's. When lesser men were still yawning at their office desks in the morning, the surgeon was displaying courage, subtlety, strength and judgment at an operating table, recovering not only tin whistles from the stomachs of children but bullets from the skulls of policemen. Of course he soaked the rich (and good luck to him!) but he remained faithful to the old tradition of aiding the poor for nothing. What greater stature could a man desire? What higher satisfaction than to see, happily going about their lawful occasions, men and women who but for his intervention would assuredly have been six feet underground?*

ANSWER TO WHAT'S YOUR DIAGNOSIS

(From page 884)

Skin lesions appeared progressed to the characteristic appearance of herpes zoster. The burning distress across the abdomen and the costo vertebral tenderness should have led to the suspicion of herpes zoster.

Physicians ought to console their patients even if the signs of impending death seem to be present. For the bodies of men are dependent on their spirits.

— Rhazes (865-925)

Cytogenetics Laboratory Services

The Minnesota Department of Health announces the establishment of a Cytogenetics Laboratory to aid in the identification of specific diseases with chromosome anomalies. This new service will be under the joint sponsorship of the Human Genetics Unit, Division of Special Services, and the Virus Laboratory, Division of Medical Laboratories.

Since the discovery in 1960 that Down's Syndrome (mongolism) was associated with the occurrence of an extra chromosome (trisomy 21), a number of diseases and syndromes have been found to exhibit chromosomal irregularities. (Kleinfelter's* and Turner's syndromes are two which show chromosome anomalies of the sex chromosomes, and there are many variations of these anomalies that have been reported.) Any individual having immature or questionable genitalia should have a sex-chromatin study done (i.e., determination of the presence or absense of sex chromatin in the nucleus of squamous epithelial cells), and if the clinical sex and the genetic sex are in confusion, chromosome studies should be done.

There are two syndromes which have been described (Trisomy 13-15 and Trisomy 17-18) in which the patients show multiple congenital anomalies specific for each of the two syndromes. While chromosomal anomalies are rare it is estimated that they are associated with about 10 per cent of all congenital malformations, about five to ten per cent of mentally defective children, and one per cent of sterility.

Procedure for Cytogenetics Laboratory Services

The Cytogenetics Laboratory will provide chromosome karyotyping for diagnostic purposes, upon referral from physicians, dentists, and health agencies, at no charge. Because of the limited number of patients which can be examined, all referrals will be screened through the Human Genetic Unit and priorities set.

1. Referrals should be sent in writing to the Human Genetics Unit, Minnesota Department of Health, and should contain all pertinent medical history, tentative diagnosis, and the reasons for requesting chromosome karyotyping.

2. The physician or agency will then be notified of the priority for this patient.

3. Arrangements will be made with the physician to obtain the required 10 cc. heparinized peripheral blood specimen from the patient. (Collecting tubes will be provided by the Department of Health.) Because cell culturing becomes difficult when the sample is over six hours old, it may be necessary for patients living any distance from the Twin Cities to have the specimen drawn in the Twin Cities.

4. Due to the culturing procedures for chromosome karyotyping specimens will be accepted only on Monday or Tuesday of each week.

5. Upon completion of the karyotyping a written report will be sent from the Human Genetics Unit to the referring source, two to three weeks after submission of the specimen.

Grand Rounds

The Use of Extracorporeal Dialysis*

(Artificial Kidney)

Several means for removal of circulating products of metabolism from the blood are available — gastric lavage, irrigation of an isolated loop of ileum, high colonic lavage, pulmonary lavage, and peritoneal dialysis.[1] All of these are less efficient than the artificial kidney. Some patients may be better suited to peritoneal dialysis which, therefore, may not be in direct competition with hemodialysis.[2] Peritoneal dialysis may be a better choice in:

1. Coagulation defects (i.e., thrombocytopenia)
2. Active gastrointestinal bleeding
3. Those without accessible vessels
4. Those with rare blood types
5. Small children and infants

In addition, peritoneal dialysis is easier, requires less personnel for maintenance and does not require a trained team or elaborate mechanical equipment. With the use of regional anticoagulation, active gastrointestinal bleeding is no longer a contraindication to artificial kidney hemodialysis.

Development of an effective therapeutic agent is based on a biphasic process. The first phase entails the development and refinement of a particular technique free from dangers and side effects. This is followed by the second phase — that of clinical application — which demands a knowledge and appreciation of the factors indicating the use of the technique.

The first phase of hemodialysis commenced in 1914 when Abel et al.[3] postulated that, in renal failure, accumulated waste products could be removed by means of dialysis outside the body. The advent of "cellophane" as a satisfactory semipermeable membrane and the discovery of heparin enabled Kolff to develop the first artificial kidney for clinical use in 1944. The period since World War II has seen a tremendous number of improvements and developments in the technical and engineering aspects of these machines. The first phase is completed in the sense that the technique and performance of hemodialysis are no longer in the experimental stage, and

*Presented as a Medical Grand Rounds at Mt. Sinai Hospital, Minneapolis, January 26, 1965.

Continued

the procedure is virtually free from any serious dangers. The routine use of hemodialysis in clinical practice has also now been firmly established.

Concept of Urea Balance

The continuous formation of urea requires its removal by the kidneys. There is, therefore, a balance between its production and removal (Figure 1).[4] When this balance is upset, accumulation of urea in the blood results. This imbalance can be the result of (1) decrease in urinary output or (2) increase in urea formation. Figure 2 is a schematic representation of the possible events when this balance is upset. The normal balance is depicted by the position of the axis A-A′. A minor upset (B.B′), provided it does not go outside the block abcd, can usually be handled by normal body compensatory mechanisms. The block abcd, is, therefore, representative of the compensatory state. However, when the upset in the balance is such that it passes out of the confines of this block (say to C-C′), treatment becomes important in order to interrupt the progression to D-D′, which is equivalent to death. The rate at which the change in position from A-A′ to C-C′ occurs influences the ultimate prognosis. Therefore if, in the early stages of renal failure, the daily rise of the blood urea level is rapid, immediate dialysis should be considered. It is the daily rise in blood urea level, rather than the absolute blood urea level, that governs the selection of patients for hemodialysis.

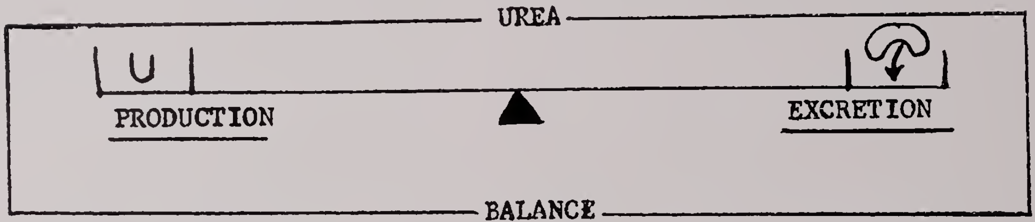

Fig. 1 — (After Nayman, 1962)

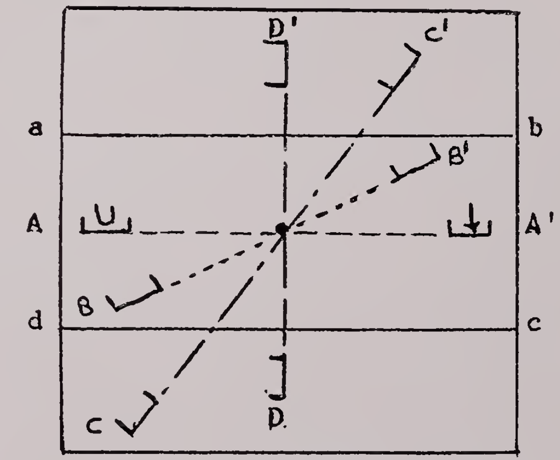

Fig. 2 — (After Nayman, 1962)

Increased Production

An increase in protein catabolism and urea production can be due to (1) trauma, (2) surgery, and (3) infection. The formation of urine is dependent upon adequate renal blood flow, glomerular filtration, tubular secretion and absorption and patency of the conducting channels to the exterior. The glomerular and tubular factors constitute the renal element, and the blood flow and conducting channels constitute the extrarenal elements.

Decreased Excretion

The causes of decreased excretion of urine are either renal or extrarenal. Renal causes are: (1) glomerular disease and (2) tubular necrosis. Extrarenal causes are: (1) inadequate renal blood flow and (2) lack of patency of conducting channels. The tubular lesion (acute tubular necrosis), trauma, surgery, sepsis, acute glomerulonephritis and reduction in renal blood flow constitute the acute lesions. Chronic glomerular disease and the uropathies are responsible for the chronic lesions.

Any of the above factors, alone or in combination, can cause renal failure, of which an elevated blood urea level is merely an isolated and single manifestation. The interplay of these factors is indicated by the concept of urea balance, and urea imbalance is an index of the factors constituting the derangement of renal failure.

Different Types of Artificial Kidneys

Abel's apparatus[3] consisted of a set of cylindrical collodion tubes through which blood from dogs could flow. The tubes, enclosed in a chamber, were bathed in saline. Hirudin, extracted from the heads of leeches, served as the anticoagulant. The collodion acted as a semipermeable membrane through which substances of small molecular weight were removed from the blood by dialysis. Quantitatively the results were poor; part of the difficulty was the thickness of the membrane.

Necheles in 1923 constructed an artificial kidney using sheep's peritoneum as the dialysing membrane. Haas in 1925, still using hirudin as the anticoagulant, first attempted dialysis of a human being; but the amount of urea removed was small.

A few attempts have been made to construct artificial kidneys from ion-exchange resin columns, but these have been only partially successful.

The four types of machines which have proved their efficiency over the course of time are the Kolff rotating drum, Alwall, Skeggs-Leonards and the Kolff twin-coil disposable kidneys.

Kolff Rotating Drum

Not until 1944 did Kolff and Berk, working in German-occupied Holland, first report on the successful use of an artificial kidney to remove significant amounts of urea and other catabolic products from patients with renal failure.[5] Blood from the patient flowed through cellophane tubing which was wrapped around a large rotating drum partially immersed in a physiological salt solution, the dialysate. Similarly constructed kidneys are still in use.

The Kolff rotating drum kidney has been modified by increasing the size of the drum and the rinsing bath, and the time of the dialysis has been reduced to 4½ hours. It is accepted that the more efficiently the dialyser unit is capable of reducing the time of the dialysis, the less the procedure-fatigue to the patient and the less time-consuming for the staff. However, it has also been shown that sudden and rapid alteration in the tissue

Continued

electrolytes can produce a deterioration in the condition of the patient, and it is better to limit the time of these more efficient dialyses rather than attempt to complete urea clearance.

In the Kolff type of kidney there is a build-up of electrolytes in the dialysing fluid bath over the course of the dialysis, and the dialysis is stopped every two hours to replace this fluid with a new solution.

Alwall

In 1947, Alwall in Sweden developed a functional kidney consisting of cellulose tubing wrapped around a wire net and enclosed by a second wire net.[6]

The lower over-all efficiency of the Alwall kidney is a serious handicap in treating patients in whom the blood urea rises rapidly between the dialyses. Alwall has compensated for the lower clearance of his machine by prolonging the time of each dialysis.

Skeggs-Leonards

In contrast to the coil kidneys are the parallel flow units. Here blood flows through several short lengths of cellophane membrane arranged in parallel. Such an arrangement offers much less resistance to blood flow, making it possible for the patient's own arterial pressure to propel blood through the system without the use of an accessory pump. Examples in use are the Skeggs-Leonards,[8] Kiil[9] and macNeill-Collins[10] dialyzers.

The Skeggs-Leonards kidney differs from the Kolff rotating drum and twin-coil disposable artificial kidney in that there is a continuous flow of blood and dialysing fluid in opposite directions for the full six hours of dialysis. Consequently, it is not necessary to stop the machine during the course of dialysis. The composition of the dialysing fluid is not altered during the time of dialysis, the fluid in the dialyser being continuously replaced by fresh dialysing fluid containing a constant concentration of electrolytes.

Kolff Twin Coil

The disposable twin-coil kidney which is presently in widespread use in hospitals throughout the world was developed by Kolff and Watschinger in 1956. The coil consists of two flattened cellulose tubes, each 10.75 meters long, enveloped in fiberglass screens and wrapped around a central cylinder. The coil is placed in a 100-liter tank containing the dialysate which is pumped up through the fiberglass screens. Arterial blood from the patient flows through the cellulose tubing, assisted by a pump, and then returns to a vein. Dialysis takes place in the coil. The dialysate consists of physiological concentrations of $Na+$, $Cl-$, $K+$, $Mg++$, $Ca++$, $HCO3-$, lactate and glucose in water. It is changed every two hours during the average six-hour "run".

Capacities of Dialysing Units

The volume of blood required to prime the dialysing unit is of considerable importance, not only to reduce the strain upon the blood bank, but also because blood itself carries risk of serious reactions.

Blood Volume

The individual blood capacities of the dialysing units are: Skeggs-Leonards, 550 ml.; Kolff rotating drum, 1000 ml.; Kolff twin coil, 1200 ml.; Alwall 1300 ml.

Size

The Alwall, Skeggs-Leonards and twin-coil kidneys are smaller and more mobile and, by a pressure differential between the blood and dialysing fluid circuits, effect ultrafiltration of fluid from the corporeal circulation. The Kolff rotating drum machine is much larger and relatively fixed and is not capable of ultrafiltering fluid from the overhydrated patient.

Urea Clearance

A comparison of urea clearance with different types of artificial kidneys is revealed in the following table:

Type of Artificial Kidney	Urea Clearance: Per Cent
Alwall	47.0
Kolff twin coil	56.0
Skeggs-Leonards	63.5
Kolff-rotating drum, modified (4½ hours)	75.0

(After Edwards, 1963[10] Modified)

Biochemical Adjustment

Urea clearance is not the only requirement for a successful dialysis as there must also be a satisfactory biochemical adjustment in the plasma composition: (1) reduction of the plasma K concentration where hyperkalemia exists to values within the normal range and preferably to approximately 3.5 to 4 mEq./L., (2) stabilization of the plasma bicarbonate levels at approximately 20 mEq./L. where the initial values are materially lower, (3) adjustment of Na, Cl and Ca to approximately low normal values. Higher levels of Na should not be sought because of the possible encouragement of water retention.

When comparing these machines, it must be remembered that a team knowledgeable in the management of these types of patients is of more importance than the type of machine used.

Mechanism

Most artificial kidneys are constructed in such a manner that the patient's blood is dialyzed against a physiological salt solution with cellophane acting as the semipermeable membrane. Waste products of metabolism such as urea and creatinine move through the pores of the membrane from a place of high concentration, the blood, to one of low concentration, the dialysate. Larger particles such as proteins, blood cells and bacteria cannot pass through the membrane.

The Kolff twin-coil disposable kidney is presently being used at Mt. Sinai Hospital. A schematic illustration of its function is shown in Figure 3.

If general anticoagulation of the patient leads to danger of hemorrhage, regional anticoagulation is used. Heparin is administered to the blood flowing from the patient to the artificial kidney and a neutralizing dose of protamine sulfate is administered simultaneously to the blood flowing from the artificial kidney back to the patient.

Indications

Extracorporeal hemodialysis has been successfully used in the following conditions:[12]

Acute Renal Insufficiency

1. Following peripheral circulatory collapse, e.g., profound hemorrhage, severe anoxia, acute pancreatitis, trauma, head injuries, severe dehydration, carbon monoxide intoxication, myocardial infarction, septicemia and post-partum acute renal failure resulting from abruptio placenta or severe electrolyte disturbance.[13]
2. Hemoglobinuria and myohemoglobinuria, e.g., crush syndrome, sickle-cell crisis, transurethral prostatectomy with hemolysis, incompatible blood transfusions, icterus neonatorum, hemorrhagic fever, severe burns.
3. Acute obstruction of ureters.
4. Selected cases of acute glomerulonephritis.
5. Hepatorenal syndrome and hepatic coma.
6. Acute renal failure supervening on existing renal disease.

Acute Poisoning

1. Nephrotoxic substances: heavy metals (mercury, bismuth, phosphorus, uranium); antibiotics (bacitracin, viomycin, etc.); leptospirosis; eclampsia; bacterial toxins, sulfonamides, serum sickness; organic compounds (carbon tetrachloride, black widow spider poisons, mushrooms, etc.)
2. Dialyzable Poisons:
    - Phenobarbital
    - Barbital
    - Secobarbital
    - Tolbutal
    - Amobarbital
    - Pentobarbital
    - Doriden (Glutethimide)
    - Bromide
    - Acetyl salicylate
    - Methyl salicylate
    - Dilantin
    - Strontium
    - Radio calcium
    - Tritium
    - Potassium thiocyanate
    - Ammonia
    - Sodium chlorate
    - Antifreeze
    - Ethyl alcohol
    - Methyl alcohol
    - Bichloride of mercury
    - Iron

It is obvious that the best results will be obtained in the above two groups of cases. These patients have reversible disease and need to be supported until spontaneous diuresis and recovery occurs, or until the noxious and toxic agent is removed.

Other Indications

1. Removal of edema and correction of electrolyte problems in severe congestive heart failure.
2. Long-term problems in the care of chronic renal insufficiency in selected cases of chronic uremia.
3. Investigation of the uremic syndrome as an experimental procedure in the laboratory.
4. In acute gouty arthritis, with refractory hyperuricemia.[18]

Acute renal failure is defined as "an advanced quantitative reduction in renal function to a point where the kidneys are unable to maintain chemical

Continued

homeostasis in the organism".[14] Acute reversible renal failure may be caused by a broad spectrum of diseases that have anuria or oliguria as their characteristic.

Many patients with acute renal failure are able to survive with meticulous attention to fluid restriction, correction of electrolyte abnormalities, therapy of infection and supportive care. However, there are two groups of patients needing extracorporeal hemodialysis for survival: (1) patients with prolonged anuria, and (2) patients with marked tissue destruction. The following are some of the indications necessitating dialysis:[15]

Clinical Criteria for Dialysis

Deterioration of Clinical Status

Dulling mental acuity, confusion, restlessness, pernicious vomiting and hiccough. Convulsions and diminishing blood pressure are late features.

Laboratory Findings:

1. Blood urea nitrogen of more than 400 mg% in medical and obstetric cases or 300 mg% in surgical cases. Some authorities do not place much value on the absolute figure for blood urea, but maintain that a daily rise of blood urea of 30 mg% or more with an absolute figure of even as low as 100 mg% is an indication for dialysis if the patient's over-all clinical status warrants it.
2. Serum K of 7 mEq./L. or more.
3. CO_2 combining power of less than 13 mEq./L.

Dialysable Toxins

1. Molecular size is small enough to diffuse through cellophane (i.e., dialysable).
2. Distribution of the substance in the body is such that it is available for dialysis from plasma (i.e., not protein-bound).
3. There is a relationship between toxicity, amount ingested and the duration of body exposure.
4. Dialysis contributes heavily to the removal of the noxious substances.

Chronic Uremia

The care of patients with chronic renal insufficiency is often ineffective. The patient with a diminishing glomerular filtration rate may be supported over periods of crisis and returned to his usual status with dialysis.

In contrast to this type of patient, there is a group of patients with more advanced deterioration of renal function who will not tolerate even minor illnesses because of marked decrease in renal reserve. Scribner[17] has pioneered methods for chronic vessel cannulation and intermittent hemodialysis in patients with terminal uremia. The concept of weekly or semiweekly hemodialysis has been applied to a group of patients with rather remarkable results. However, the cost of keeping up such a procedure for any length of time is a prohibitive factor.

Group IV: Removal of Edema

Ultrafiltration is a relatively new method available for the reduction of excess body water in patients refractory to diuretics.[19]

Complications

Rosen et al.[20] describe a dialysis disequilibrium syndrome. This syndrome is more severe when the plasma urea is very high before dialysis and manifests itself when the blood chemistry improves. First evidence is increasing lassitude, headache, drowsiness and confusion. In more severe cases there is an increase in blood pressure, pulse rate and respiratory rate. This is actually a "water intoxication" resulting from the fact that urea clearance during dialysis lags behind in the cerebrospinal fluid. This "urea gradient" results in cerebral edema.[21]

Atrial fibrillation and flutter during hemodialysis and terminating shortly after cessation of the dialysis may result from right atrial distension due to the rapid flow of blood from the coil to the patient.[22] The almost immediate conversion from atrial fibrillation to regular sinus rhythm on the termination of the dialysis indicates a hemodynamic mechanical etiology rather than blood chemical alterations.

Hypotensive reactions sufficiently severe to warrant the use of pressor amines are known to occur when blood is used to prime the dialyser. Mechanisms underlying this reaction are not clear, but use of a solution of 5% human serum albumin in 0.9% NaCl for priming avoids such reactions.[23] The apparent efficacy of albumin solution in avoiding such reactions has not been explained.

Case Histories

Case No. 1

A 41-year-old white woman was admitted to Mount Sinai Hospital December 11, 1964, with a history of severe hypertension for several years and probably beginning during one of her many (10) pregnancies. She had not responded to medical management of the hypertension, and approximately eight weeks prior to admission had begun to have epigastric pain, more severe hypertension, and anemia down to 7 gm. of hemoglobin. Her blood urea nitrogen was 16 mg% in November 1964, had risen to 69 mg% by 12/2/64, and had increased further to 110 mg% at the time of her transfer to Mount Sinai Hospital on 12/11/64. Ten days before admission she had had a hypertensive crisis with convulsions. Extensive investigation including GI X rays during November 1964, failed to reveal any other basis for the anemia. A bone-marrow examination revealed erythroid hyperplasia. Treatment with several antihypertensive drugs failed to lower her blood pressure. Serum K had risen to 6.6 Meq/L a week before admission.

Examination on admission revealed blood pressure of 210/120 in both arms. The patient was confused and lethargic. There was no dyspnea or orthopnea. Fundi showed arteriolar narrowing, AV nicking, and many small hemorrhages and exudates. There was no papilledema. There were bilateral basal pulmonic rales. Heart tones were clear with a sinus rhythm of 80/min. There was widely split second heart sound at the apex and base. The heart was markedly enlarged to the left, and there was a leathery systolic squeak consistent with a pericardial friction rub. The liver was enlarged 6 cm. below the costal margin. There was no splenomegaly. The abdomen was otherwise negative. There was no peripheral edema. The tongue was somewhat dry and there was no evidence of overhydration. On admission she had 8.3 gm% hemoglobin, normal total and differential white blood count, 2+ albuminuria, blood urea nitrogen 117 mg%, serum Na 112 Meq/L, K 3.2 Meq/L, serum creatinine 13 mg%, uric acid 15.3 mg%, CO_2 content of 23 Meq/L, chlorides 69 Meq/L, serum Ca 7.3 mg%, P 10.7 mg% and a normal liver profile. A 24-hour urine (950 ml.) had a total of 8.7 Meq Na, 21 Meq K, 1.8 Meq chloride. She was put on tetracycline and later on chloromycetin to control a urinary tract infection due to E. coli.

She was treated with large doses of guanethidine, restricted fluid intake, 1000 - 1500 ml/day, and hypertonic saline. Retrograde pyelogram revealed no evidence of obstruction. By 12/15/64 it was apparent that she was clinically deteriorating. She was "run" on the artificial kidney for six hours the same day. Before the dialysis blood urea nitrogen was 123 mg%, uric acid 13.7 mg%, CO_2 content 22 Meq/L, chloride 81 Meq/L, Na 121 Meq/L, K 4.8 Meq/L, Calcium 8.1 mg% and P 6.4 mg%. Following the

Continued

dialysis, blood urea nitrogen was 59 mg%, creatinine 6.2 mg%, uric acid 6.8 mg%, CO_2 content 26 Meq/L, chlorides 92 Meq/L, Na 133 Meq/L, K 3.7 Meq/L, Ca 10 mg% and P 6.5 mg%.

After dialysis, as much as 200 mg. guanethidine, 425 mg. Apresoline, in addition to 10 mg. reserpine daily failed to bring her blood pressure down. By 12/17/64 she was anuric with blood urea nitrogen rising. Because of her failure to respond it was felt that she had terminal and irreversible renal failure, and it was decided not to dialyse again. The family elected to take her back to the local hospital. Renal biopsy was not attempted because of the extreme hypertension.

The patient expired two days after return to the local hospital. Autopsy revealed findings consistent with malignant (accelerated) nephrosclerosis. Her blood urea nitrogen before death rose to 172 mg%, and she remained oliguric.

Case No. 2

This 57-year-old white man, who was admitted to Mount Sinai Hospital January 22, 1965, had had a myocardial infarction three years before and had suffered from recurrent congestive heart failure for two years. He had been reasonably well controlled with salt restriction and intermittent diuretics. He had had no digitalis since May 1964. For 10 days before admission he had had marked oliguria, increasing edema, lethargy and dyspnea. On 1/20/64 he was admitted to another hospital and for the next 48 hours his total urinary output was 93 ml. He was then transferred to Mount Sinai Hospital for hemodialysis.

Examination on admission revealed blood pressure 110/70 in both arms, respiratory rate 26/min., and apical rate 88/min., regular. The fundi showed moderate arteriosclerotic change. Neck veins were distended; the abdomen was tense with ascitic fluid, and there was edema extending up to the thighs. There were crepitant rales at both lung bases and the heart was markedly enlarged.

On admission, blood urea nitrogen was 126 mg%, CO_2 content 17 Meq/L, chlorides 101 Meq/L, Na 138 Meq/L, K 5.7 Meq/L. A small amount of urine was obtained and revealed 1+ albumin. Electrocardiogram showed changes consistent with left ventricular strain. Chest revealed marked cardiac enlargement and pulmonary congestion.

Within four hours after admission, the patient was put on the artificial kidney and had a uneventful six-hour run. The artificial kidney blood outflow was partially clamped during the run to produce ultrafiltration and removal of body water. At the end of the dialysis he had lost 10 lbs. in body weight (from 151 lbs. down to 141 lbs.). Blood urea nitrogen was 82 Meq/L, Co_2 content 23 Meq/L, Cl 97 Meq/L, Na 137 Meq/L, and K 4.8 Meq/L. During the 24-hour period following dialysis his urinary output was 2980 ml. with specific gravity of 1.007 - 1.010. During the five days after dialysis he had had a urinary output averaging 3000 ml. per 24 hours and his weight had decreased and stabilized at 126 lbs. He had lost a total of 25 lbs. in this five-day period, and his ascites and peripheral edema had disappeared. Blood urea nitrogen had risen to 126% by the second day post dialysis but fell to 60 mg% by the sixth day. He was alert and no longer dyspneic. He was kept in negative water balance until the fourth post-dialysis day, at which time fluid replacement was kept equal to losses. Serum electrolytes have been maintained at normal levels without difficulty.

This patient probably represents a case of arteriosclerotic heart and kidney disease with superimposed severe and acute congestive heart failure associated with further renal decompensation and anuria. He was moribund on admission. Hemodialysis appears to have reversed his progressing heart and renal failure and at least temporarily returned him to his previous stable state.

Abstracts, Briefs and Commentaries

THE FATE OF DACRON VASCULAR GRAFTS

The authors present their data on 67 Dacron grafts removed in a period of from one to seven years in 58 patients. The grafts were removed for a variety of reasons (aneurysmal formation at the site of anastomosis and death of the patient from other causes). The important laboratory studies included electron microscopy as well as conventional histologic studies of the specimens.

The characteristic microscopic feature was the formation of two distinct layers, an inner and outer cellular membrane, surrounding the Dacron prosthesis and well incorporated by fibrous tissue into the Dacron interstices. There was only rare endothelialization on the inner surface of the graft beyond the immediate area of the anastomosis. The majority of the inner portions of the graft were lined by fibrous tissue. There was one degeneration by lipoid material but no evidence of calcification in the inner layer.

The authors then compared the fate of prosthetic graft in man to that of the graft in animals. In general the grafts in man fared better, in that the inner lining remained thin, did not proliferate unduly and did not occlude the graft, as so often happened in the pig. In man, the grafts performed well in various locations in the abdominal aorta and extending into the region of the popliteal artery.

The authors presented their procedures with multiple pictures and diagrams. It is interesting to note that they would operate again on the patients who developed aneurysmal formations or occlusions beyond the site of the original graft. A most impressive fact is that the prosthetic vascular grafts functioned well in the absence of an endothelial lining and there was no report of a slough of the false lining with secondary occlusion of the graft. My own experience with Dacron grafts indicates that this is an excellent substitute at least in the interabdominal vessels. The use of the synthetic prostheses in bypasses of the femoral and popliteal arteries is not as yet clarified in my mind, and vein grafts are still preferred.

CANCER OF THE BREAST IN OLD AGE

Haagensen and associates have studied a series of 556 consecutive radical mastectomies of all ages. They used the Columbia clinical classification in which Stage A reveals no clinically axillary adenopathy. Stage B reveals lymph nodes less than 2.5 cm. Stages C and D are more advanced.

They found that the results indicate a better prognosis in the older age group (over 65) than in the younger group. They also found that the operative mortality was not increased and there was no operative death in the older age group. It was their opinion that advanced cardiovascular disease, diabetes or old age was not a contraindication to radical mastectomy, and they came to the logical conclusion that radical mastectomy is the treatment of choice for operable mammary carcinoma in women, even in the aged.

The five and ten-year survival rate in the group of aged patients, after elimination of those dying of intercurrent disease, was 78.5 and 55.2 per cent, respectively. The survival rate in the younger group was less than that.

One occasionally hears it said that a patient is too old to tolerate a radical mastectomy. This study of Haagensen et al. clearly points out the futility of taking such a pessimistic attitude toward women who have attained their 65th birthday. Indeed, it is probably true that very few 65-year-old women consider themselves to be aged.

Simple mastectomy has almost no place in the armamentarium of a trained surgeon.

AMELOBLASTOMA

The clinical course and the follow-up study of 33 patients with ameloblastoma are reported. The tumor arose in the mandible of 27 patients, and in the maxilla of six. The patients, when first seen, were classified into two groups: 14 patients who had recurrent disease, and 19 who were not previously treated. Of the 14 patients who had recurrent disease, all had had initial local excision of the tumor; four had had another local procedure, all of whom had recurrence. Of the patients who had wide resection of the tumor and the jaw, seven were cured, and two were lost to follow-up. One died of distant metastases. Of the 19 patients with previously untreated ameloblastoma, 14 had had local removal of the tumor, and eight had recurrences. Only four remained free of tumor. Three had wide excision of the tumor and adjacent bone, and all remained free of tumor. Two were lost to follow-up. Because ameloblastoma of the jaw can recur locally, and can extend widely and cause death, an adequate resection of the tumor and jaw is recommended as the treatment of choice.

VAGINAL EXAMS DURING LABOR

A bacteriologic study of vaginal examinations in labor was made at the Santa Clara County Hospital on about 1000 women, about half of whom had vaginal examinations while the others had rectal examinations. On admission to the maternity ward every patient's vulva was scrubbed with soap and water and then shaved. Vaginal examinations were performed in half the labor rooms and rectal examinations in the other half; the women were assigned to one or the other group alternately.

Old rubber gloves were worn for both vaginal and rectal examinations; they were autoclaved and kept in sterile canisters, but no further effort was made to keep them sterile. Before vaginal examination 1:4000 aqueous benzalkonium chloride was poured over the vulva. Only in cases of gross contamination was this repeated.

The examiners did not scrub their hands before putting on the gloves, but when it was desirable to do a vaginal examination on a patient from the rectal group she was taken to the delivery room and fully prepared and draped, and the examiners then scrubbed their hands for three minutes with hexachlorophene soap.

The patients were routinely discharged on the fourth post partum day unless they were febrile; if they had fever they remained in hospital until their temperature had been under 100.4° F for at least 24 hours.

For the bacteriologic examination each patient on the third post partum day was placed on an examination table; a sterile speculum was inserted into the vagina; the cervix was visualized and a specimen was taken from the endocervical canal, with care that it was not contaminated by vaginal discharge.

Little difference was found between the two groups in factors that might influence morbidity. Statistically the vaginal group had a somewhat longer period between rupture of the membranes and delivery, and slightly more examinations than the rectal group.

Among the 543 patients examined vaginally there were 18 cases of morbidity according to the standard adopted; five of these had marked breast engorgement with severe tenderness, one had pharyngitis and another had severe contact dermatitis. Urinalysis in all cases was negative and there was no clinical evidence of endometritis. Among the 514 patients examined rectally during labor there were 13 cases of morbidity, one probably due to breast engorgement.

In the vaginal group a streptococcus was cultured in 11 of 17 cases and *Escherichia coli* was cultured in one. In the rectal group *E. coli* was cultured in eight of 12 cases and a streptococcus was found in one. Evidently seeding from the fecal area was the greater when rectal examinations were done. No statistical difference was found in the morbidity of the two groups.

There seemed to be no need for more extensive preparation of patient for a "sterile" vaginal examination. The simple procedure outlined here appeared to be as safe as rectal examination, and the results may help to dispel the deep-seated fear of doing vaginal examinations on patients in labor.

INFECTIOUS MONONUCLEOSIS

Twenty-six of the 100 cases of infectious mononucleosis treated in a Naval Hospital between March, 1961, and May, 1962, were included in a double-blind study of the treatment of this disease. They included a placebo-treated group of five cases; aspirin-treated, eight cases; chloroquine-treated, five cases; and prednisone-treated, eight cases.

From analysis of the fever, signs and symptoms and the duration of illness, total hospital stay and stay in hospital after treatment, it was concluded that none of the drugs, with the possible exception of intravenous steroids (which were administered to two patients because of airway obstruction from pharyngeal edema), were beneficial to the basic disease.

The best treatment for infectious mononucleosis is symptomatic. Some patients obviously have secondary invaders in the tonsils and pharynx. The pathogens detected in this series were varied and mostly incidental. This complication is best treated with the appropriate antibiotics as determined by culture.

Jaundice, the usual manifestation of hepatic complications, was present in nine cases. It is best treated with rest in bed and a high-calorie diet.

Only one case of splenic rupture has been seen at this hospital among more than 500 cases of infectious mononucleosis in the last seven years. This followed over-vigorous palpation of the spleen. It is recommended that only one person should palpate the spleen and he should do it gently and not more than twice a week.

PROTEIN ABNORMALITIES IN ULCERATIVE COLITIS

An antinuclear factor, which has been found in lupus erythematosus patients and their families, has also been found in ulcerative colitis. The sera of 98 subjects from 34 families with ulcerative colitis were examined for the presence of antinuclear and rheumatoid factors, thyroid antibodies, and positive lupus erythematosus (LE) latex tests. These were compared with a contratest group of relatives of gastric cancer patients. The antinuclear factor was found in 23% of the ulcerative colitis families, but in only 3% of the contratest group. The incidence of rheumatoid factor, thyroid antibody, and LE latex was the same in both groups.

MALLORY-WEISS SYNDROME

Hemorrhage from gastroesophageal lacerations caused by vomiting is known as the Mallory-Weiss syndrome. A review of the literature is presented and three new cases are reported. These lacerations may follow any event that brings about a marked increase in intra-abdominal pressure, such as vomiting, coughing, straining at stool, blunt external trauma, etc. It appears that this syndrome is frequently unrecognized in many patients with self-limited gastrointestinal bleeding. Only those cases requiring surgery or endoscopy have been recognized to date and reported as "rare" examples of Mallory-Weiss syndrome. This syndrome should be looked for in any patient with upper gastrointestinal bleeding and a history of vomiting or straining before bleeding.

SWIMMER'S ITCH

Swimmers often develop skin lesions, usually with considerable pruritus, caused by *Trichobilharzia ocellata;* at the second larval stage of this organism it penetrates the epidermis and the lesions result. The condition is called swimmer's itch.

The eruptions start on the lower legs and extend upward as far as the abdomen, rarely further. Erythematous macules 2 to 200 mm. in diameter appear a few hours after the swimmer has left the water. They are pink or red with a small purple center. In 10 or 15 days the lesions gradually clear up, leaving no trace of pigmentation.

The trematode infests the digestive tracts of wild and domestic ducks and probably of other aquatic birds as well. The larvae which penetrate human skin are *Cercaria elvae.*

The condition is mild and transitory, so that therapy is hardly indicated. Washing with hot acidulated water, and bland powders or lotions have been helpful, also local applications of camphorated or mentholated oils, which might be of use prophylactically.

DIGITAL ISCHEMIA

Repeated trauma to the hand may result in severe ischemia of the digits. In the heavily industrialized area of Detroit, eight personal cases were seen in ten months, and the records by Henry Ford Hospital showed two others. Nine of these patients were skilled workers in the automobile and other industries, and eight told of repeated trauma to the dominant hand incurred at work.

In increasing order of frequency these patients complained of rest pain, Raynaud's phenomenon, paresthesia in the affected fingers, coldness and nonhealing ulcers. Two patients had no signs of ischemia; the other eight had evidence of subcutaneous infarction, cyanosis, positive Allen's test, absent radial or ulnar pulsations, ischemic petechiae and hypesthesia.

Atherosclerosis, thromboangiitis obliterans and cervical compression syndrome were excluded. None of the patients had scleroderma or other systemic illness and no source for repeated emboli could be found. For medicolegal reasons arteriograms were occasionally necessary to prove that the symptoms were caused by arterial disease.

The treatment of this disorder requires the patient's close cooperation. In cases where symptoms of Raynaud's phenomenon were the only ones, therapy was conservative, namely the avoidance of further trauma to the hand, abstinence from tobacco and the provision of adequate warmth and protection for the injured member. Occasionally phenoxybenzamine was given by mouth as adjunctive therapy.

When there was severe ischemia, particularly if ulcers were present, upper thoracic sympathectomy was done with marked benefit. The most important aspect of any treatment is the avoidance of repeated trauma to the hand.

This syndrome is not rare, and physicians should recognize its importance as an industrial disease.

THE COLD-WATER TREATMENT OF BURNS

Recent studies[1,2] indicate the efficaciousness of the cold-water treatment of burns. The experimental studies done on animals reveal that the surface temperature of the skin remains elevated for a considerable period of time after the burning instrument has been removed. If no treatment is given, the effects of this prolonged period of heat cause injury to the underlying tissue and death to the cells, thereby resulting in progressive tissue destruction over a period of several days and long delay in the healing process.

In the animals that were treated with cold packs or cold immersion, the surface temperature was very promptly diminished, and this cooling of the tissues resulted in less cellular damage and consequently quicker healing of the burn.

It was also observed that the effects of the burn lasted longer if clothing objects were on the skin.

Some of the conclusions drawn from these studies indicated that the tissues are subject to longer heat exposure than the actual duration of the burn, that there is continuous degeneration of the skin and underlying tissues of the untreated animal, which continues for several weeks after thermal injury, and that even delayed treatment with cold packs should be carried out immediately or as soon after the burn as possible.

Ice-cold water should not be used except for minor burns. The cold-pack treatment consists of water at approximately 15 degrees centigrade.

INFECTIOUS DISEASES OF CHILDREN — Third Edition. Saul Krugman, M.D., Robert Ward, M.D., C. V. Mosby Co., St. Louis, 1964.

The need for this third edition within seven years of a book devoted to the common infectious diseases of children indicates that the capacity for change in the texture and course of these disease is both great and rapid. The value and efficacy of routine immunizations and the power of the sulfonamides and antibiotics in modifying disease are such common knowledge as to be taken for granted. The progressive elimination of paralytic poliomyelitis since the widespread use of the Salk killed and the Sabine live attenuated polio virus vaccines is sufficiently recent to be recognized as dramatic. The potential of the live attenuated measles virus vaccine is yet to be realized, and other live attenuated virus or killed virus vaccines are yet in the stage of development.

As important as these preventive and therapeutic methods have been in altering the course of disease, newly developed diagnostic techniques, particularly those dealing with the virus diseases, have established specific virus agents as the causative agents for new clinical syndromes. Finally, the emergence of bacteria which are resistant to many of the commonly used antibiotics is yet another factor in the rapid metamorphosis of disease.

It is a tribute to the clinical and laboratory experience of the authors and the rapid workmanship of the publisher that this book is up to the minute in its factual information and appears destined to continue as a standard reference describing the common infectious diseases of children. It will continue to be a valuable and eventually thumb-worn book for those who deal with the health of children, whether they are pediatricians or general practitioners.

The chapters "Diagnosis of Acute Exanthematous Diseases" and "Control of Communicable Diseases" are excellent and I believe would be better placed as the opening two chapters of the book than as the closing chapters, but to dispute their location would be quibbling. If this book does have any serious limitation it is not in what is included in the text, for Drs. Krugman and Ward have discussed with authority those diseases with which they have extensive personal experience. However, the elimination of such important diseases as tuberculosis, syphilis, leptospirosis, and the mycotic infections prevent this book from being a comprehensive text on infectious diseases of children. When a future edition is contemplated, it might be well for the authors to seek a third author who can write on these diseases with the same authority in which they have encompassed the majority of the infectious diseases of childhood.

This book is to be recommended as well worth the purchasing price of $15.75.

COUNSELING IN MEDICAL GENETICS — By Sheldon Reed, Ph.D. 2nd Edition. W. B. Saunders Co., Philadelphia, 1963; 278 pages.

Sheldon Reed is the director of the Dight Institute for Human Genetics at the University of Minnesota. His book is an authoritative reference on the probability of various heritable defects in different clinical situations. As Reed points out, the time has come when physicians must be prepared with the correct answers to the questions put by prospective parents concerning the probability of transmitting various defects. The parents of an anencephalic monster would be pleased to hear that "lightning doesn't strike twice in the same spot" but not so pleased to see a repetition of the genetic disaster. The chapters are illustrated with case histories, the counseling, and the outcome. I cannot quarrel with the counseling as far as it applies to genetics. However in some of his case histories the counseling, though genetically sound practically, may be dangerous to the family. In one situation in a family of three boys, two with club feet, the father wanted more children. The counseling suggested the mother feign illness and let the father learn what it means to take care of the children! This, says Reed, "is a most educational experience, beneficial for all males who are overly eager for the women to produce and care for large families." This is a feminine weapon in the battle of the sexes and a two-edged one just as likely to incise the wielder.

RICHARD B. McHUGH, Ph.D.†
ANNE C. KIMBALL, Ph.D.‡
HENRY BAUER, Ph.D.***
Minneapolis, Minnesota

In recent years evaluation studies in many areas of laboratory work have become a "way of life." Numerous evaluations have been conducted by such organizations as the Communicable Disease Center of the U. S. Public Health Service, the American Society of Clinical Pathologists, state societies of clinical pathologists, and state societies of medical technologists. Departments of health in many states, including Minnesota, have conducted such studies on a short-term or continuing basis.[1,2,3,4,5] The primary emphasis of these surveys has been placed upon accuracy and/or precision of performance in the particular laboratory area.

The major purpose of the present study was to investigate the effectiveness of technical consultation — brief but intensive in character — as a method for improving the accuracy and reliability (i.e., precision) of results of clinical chemistry determinations. The study was initiated in June 1961 by the State Department of Health in 110 volunteer hospital laboratories throughout the state of Minnesota.

This study evolved from an earlier survey[6] conducted by the Department of Health to obtain information regarding existing laboratory personnel, facilities, and technical procedures. This basic information was deemed necessary for the planning of programs which might be effective in improving

Continued

patient-care services through the betterment of work done by existing personnel. One of the recommendations proposed as a result of this survey was the establishment of consultation services in laboratory techniques, particularly in rural areas.

The accuracy and precision of the values reported by participants were determined over a period of 22 months in 18 separate evaluations. The results obtained from these surveys were used to examine the effects of participation in the study as a whole, as well as the effects of consultation.

Review of the Literature

Only in the past 15 to 20 years has increasing emphasis been placed on the accuracy and reliability of results obtained from clinical chemistry laboratories. A number of surveys have been conducted in an effort to evaluate the accuracy and precision of chemical determinations and all have shown a need for improvement. In 1947 Belk and Sunderman[7] showed that more than 50% of the results obtained in their survey in Pennsylvania were unsatisfactory and that gross errors were made in many cases. Shuey and Cebel[8] reported similarly unsatisfactory results in Army and Air Force Hospitals in 1949.

Snavely and Golden[9-11] conducted three surveys for the Connecticut Society of Pathologists in 1949, 1951, and 1952. Results of the first survey of 21 hospitals showed that more than one third of the results were in error. The second survey included 28 hospitals and 13 commercial laboratories and showed 46% of the results outside the allowable limits. The third survey showed 35% of the results for 34 hospitals and 17 commercial laboratories in error.

Wootton and King[12] (1953) demonstrated a large disagreement in results between 21 different English hospitals examining the same specimen. An international trial was reported by Wootton[13] in 1954, in which laboratories in several countries were requested to perform tests on samples of freeze-dried horse serum as well as an accurate dilution of it. Results indicated the laboratories could compare two solutions more precisely than they could determine the true value of the constituent.

Several states conducted continuing surveys in compliance with laws governing approval of laboratories and personnel. The results of a California survey[4] of hemoglobin determinations indicated that reports were more precise than accurate and suggested a value of 5% for acceptable limits. The State Department of Health in Maryland[5] has published the findings of its survey in its Laboratory Bulletin. These results have repeatedly shown needs for improvement.

A number of evaluation studies have been carried out in Canadian laboratories. In 1955 Tonks and Allen[14] reported data on the accuracy of glucose determinations. In the first group, 25 out of 30 determinations were within acceptable limits, but in the second group only about one half of the results were acceptable. Extreme discrepancies occurred in both groups. In another study,[15] 17 out of 28 glucose determinations were not acceptable. More recently Tonks[16] has expanded his plan of study to include 170 laboratories from across Canada. These laboratories from hospitals of 100 beds or more made a total of 3762 analyses for eight components of freeze-dried serum. Over 40% of the values obtained were unacceptable by standards which were not overly strict.

The awareness of poor performance has caused some laboratories to seek means of improving the accuracy and precision of their results. Levey and Jennings[17] were the first to introduce the concept of quality control charts to monitor the quality of work done in the clinical laboratory. Since that time the applications of various types of quality control in the laboratory have been well-documented in the literature.[15,16,18-35]

Benenson et al.,[19] Freier and Rausch,[23] MacDonald et al.,[28] and Schneider[29] have published results of their experiences with continuing quality control programs, indicating the acceptable limits which they have been able to maintain during the period of control evaluation as well as the percentage of runs out of control.

Campbell[30] discusses a program organized by the Department of Health in Alberta to train laboratory aides in small rural hospitals in procedures for determining blood glucose, urea nitrogen, bilirubin, and prothrombin time—tests most frequently requested by physicians. Effectiveness of the program was ascertained by incorporating a quality control program which was carried out by participants upon returning to their own laboratories. Results early in the first year of operation indicated that 57% of all results were unacceptable, but 12 months later this figure was reduced to 18%. The over-all figure for the year for 1131 determinations was 32% "wrong" results. Experience with the program indicated that continuous operation of the quality control plan was necessary to maintain good performance.

With the exception of these reports, there is almost no information available in the literature concerning efforts to improve laboratory performance through workshops, consultation, or in-service training. Consultations in various areas of laboratory work was given to laboratory personnel in Georgia.[36] In clinical chemistry this was limited to directions in checking colorimeters and spectrophotometers, use of College of American Pathologists standards for calibration, and techniques for blood sugar and nonprotein nitrogen determinations. Effectiveness of the consultation was not evaluated.

Materials and Methods

Over 200 hospitals in the state were invited to participate in the study. Those agreeing to participate included 106 licensed general, two government-owned, and two special hospitals. Prior to initiation of the study, approval was obtained from the following state organizations: Minnesota State Board of Health, Minnesota Society of Clinical Pathologists, Minnesota Society of Medical Technologists, and Minnesota Hospital Association. Assistance in planning was given throughout the study by a technical advisory committee appointed by the Minnesota Society of Medical Technologists.

Plan of the Study

A total of 18 surveys were carried out over a period of 22 months beginning in June 1961. The study was designed to have three phases, each of which was to be evaluated with the results from six surveys. Phase I was known as the preconsultation period and the results from the Phase I surveys were used to establish a baseline of performance for individual laboratories. Consultation visits were given to selected laboratories during Phase II. The survey results from Phase III, the postconsultation period, were used to evaluate the effectiveness of consultation in visited hospitals, and the continuing performance in other hospitals after more than one year of participation.

Participants were asked to analyze two types of specimens. Samples for hemoglobin determination were prepared from outdated human blood from a blood bank.[35,37] The plasma was removed and the red cells were washed with normal saline and lysed with Triton X-100. Reagent-grade glycerol was added to dilute the final solution of hemoglobin to the desired concentration. After thorough mixing and filtering, the hemoglobin solution was dispensed in glass vials in 3-ml. quantities and stored at −20°C. until specimens were mailed.

Samples of lyophilized human serum* obtained commercially were analyzed for glucose, calcium, chloride, urea nitrogen, total protein, uric acid, and cholesterol. Both sample preparations were found to be quite stable and well suited to survey use. Selection of the determinations was based on results of a 1959 survey[6] which indicated that these tests were performed by the greatest number of hospitals in the state. The lyophilized serum bottles were coded X-1, 2,—18 and the lysed red-cell sample bottles were coded H-1, 2,—18. Both were labeled "Minn. Dept. of Health Chemistry Evaluation Sample." No arrangements were made to have the samples handled as "blind"

---

*Seven special lots of Versatol, Versatol-A, and Versatol-A Alternate were obtained from Warner-Chilcott Laboratories, Morris Plains, N. J., for the study. These materials were prepared by removing or reducing various constituents in pooled serum to a known level by selective dialysis, then adding weighed amounts of these constituents back into the pools. The materials were then freeze-dried (lyophilized in glass containers). Five ml. of distilled water were added to each vial to reconstitute the serum.

*Specimens were not distributed in December of 1961 and February, April, and June of 1962.

specimens, because reconstitution of the lyophilized sample would have presented additional problems in small hospitals.

The concentrations of constituents in the lyophilized serum samples ranged from normal to varying degrees of abnormal values with one exception. Due to the insoluble nature of cholesterol, it was not possible for the manufacturer to prepare these samples with the higher amounts of cholesterol normally found in serum. The target values supplied by the manufacturer were considered to be true values for each constituent. Three lots of serum containing concentrations of constituents within normal range were used for nine surveys. Four lots of serum containing abnormal concentrations were used for the other nine surveys. Each lot was used at least twice. Eight lots of lysed red-cell samples were prepared to contain concentrations of hemoglobin which were within normal range or abnormally low. Each of these lots was used for one, two, or three surveys. The median of values reported by participants was used as the target value for each hemoglobin survey. The Communicable Disease Center in Atlanta, Ga., served as a reference laboratory for hemoglobin determinations. Their results were nearly identical with the median values reported by participants for each survey.

With the exception of four months* during Phases I and II, specimens and report forms were mailed to participants on the third Monday of each month. Participants were requested to carry out only those determinations performed routinely in their laboratories and to return their results within three weeks after specimens were received. Replicate determinations were not requested, although many laboratories reported duplicate and sometimes triplicate results.

Monthly reports giving the target values of the constituents and the mean, median, range, and standard deviation of the reported values were prepared and sent to participants on the Friday, 26 days after the specimens were mailed. Results received after the deadline were not included in these calculations nor in the data presented here. It was felt that returning reports to participants at a specific time following each survey would help to maintain interest and participation throughout the study. Receipt of the report prior to mailing the next specimen would also allow laboratories which had reported results with large errors to do a certain amount of trouble-shooting in an attempt to correct their problems before analysis of the next specimen.

At the end of each phase, a progress report was sent to participants giving summary tables and histograms of the results. Laboratories were identified by code numbers which had been assigned at the beginning of the study. Laboratories were required to return results on at least three surveys during each phase in order to be included in the remainder of the study.

Selection of Comparison Groups

In order to give each laboratory a single value which could be used for rating purposes, average "Z" scores were determined. At the completion of Phase I, "Z" scores* were computed for each laboratory on each determination result reported. These were then averaged, regardless of the number of determinations performed or the number of surveys (out of six) reported on. The laboratories were then arranged on a scale according to increasing values of average "Z" scores. The highest performing one third of the laboratories (i.e., those with the smallest average "Z" scores) were defined as the Criterion Group — those laboratories which were reporting the most satisfactory results on the average during Phase I. The remaining laboratories were randomly assigned to either the Consultation Group (the group receiving consultation visits) or to the Control Group. The Control Group represented those laboratories which showed an average performance similar to that of the Consultation Group at the end of Phase I, but whose improvement during Phases II and III would stem from self-help only. This design, the Completely Randomized Design, ensured the lack of systematic bias in allocating the laboratories to groups.

The laboratories were asked to complete

$$*Z = \frac{\text{Participant's Value} - \text{Target Value}}{\text{Standard Deviation}}$$

questionnaires at the beginning of the study, which requested information regarding the administration, training of personnel, type of equipment and supplies used, the methodology used, and other items. The Consultation and Control Groups were found to be similar with regard to working characteristics, geographical location, and average "Z" scores.

A second questionnaire was sent to all participants at the conclusion of the study in order to determine any changes in characteristics during the 22 months. Participants were also requested to list changes in personnel, equipment, etc., on the monthly report forms.

Consultation

A consultant clinical chemist made at least three visits to each hospital laboratory in the Consultation Group during the months of May through October, 1962. Consultation consisted of reviewing those methods for determinations where large or consistent errors were found in the participant's results. Such things as technique, standardization of instruments through calibration with freshly prepared standard solutions, stability and source of reagents, calculation of results, and possible sources of error in the methods and instruments were discussed. On occasion it was necessary to demonstrate the calibration of an instrument or to supply the procedure for a more reliable method than the one in current use.

Workshops were given on five alternate Saturdays during August, September, and October, 1962. Invitations were sent to laboratory personnel in all visited hospitals. Most of the laboratories sent one or two persons to one of the workshops. Two determinations, chloride and urea nitrogen, were discussed in detail and performed by participants with supervision and aid from the consultant chemist.

Analysis of Results

With the exceptions of glucose and cholesterol, methods *per se* were not evaluated in the study. Two categories were used for reporting glucose results: True Glucose, measured by methods such as that of Nelson[38] and Somogyi,[39] and Total Reducing Substances, measured by methods such as that of Folin and Wu.[40] Target values for each category were supplied by the manufacturer.

Cholesterol results were also placed in two categories. Class A included cholesterol results obtained by the Abell[41] or the Schoenheimer and Sperry[42] methods. These extraction methods were found to give more accurate results by correcting for chromogenic interference — a possible cause of erroneous results. Class B represented all other results, i.e., those obtained by various direct methods (e.g., Pearson, Stearn, & McGavack[43]), methods used by too few laboratories to be separately evaluated, or methods found to give values covering a wide range (e.g., Bloor[44]).

The allowable errors were chosen by arbitrarily assigning percentage limits for each determination (see Table 3). These limits were arrived at through consideration of the acceptable limits used by other authors[4,5,7-11,16,23,45] and were felt to be not overly strict. These limits were used for both accuracy and precision analysis.

Accuracy was defined as the ability of a laboratory to obtain results which agreed with the true values of the constituents. As mentioned earlier, the target values supplied by the manufacturer represented the true values for purposes of this study. These target values were used to compute the acceptable limits, and accuracy was then evaluated for each group by determining the percentage of laboratory results falling within acceptable limits.

Reliability, or precision, was defined as the ability of the laboratories to obtain closely repeatable results. Since precision indicates the degree of spread of the results from the average, the *mean values* of the results reported for each constituent were used to compute acceptable limits for this analysis.

The significance of changes in performance from Phase I to Phase III was determined for each group by binomial proportion analyses with probability values being obtained from a table of the normal distribution.[46] Phase II was omitted from the analysis

Continued

of results because consultation occurred during that phase. Effectiveness of consultation was measured by computing *net change* in performance — defined as the change demonstrated by the Consultation Group, corrected for the change demonstrated by the Control Group.[47]

Tables of statistical inter-relationships were used to compare technical and environmental factors with laboratory performance at the end of the baseline period.[46,48] The effect of consultation as it relates to training of personnel was also examined by this method. The questionnaires completed by the participants provided the information needed to rate each laboratory according to training of personnel, availability of a pathologist, and hospital size as indexed by bed category and chemistry workload.

Results and Discussion

Description of the Study Population

Participation According to Hospital Size

Approximately 60% of the hospital laboratories in the state participated in the study at the outset. Table 1 shows the degree of participation according to hospital size as indexed by bed category. Of the 110 laboratories that agreed to participate, 90 completed the study. Of the 20 dropouts during the course of the study, ten occurred during the baseline period, Phase I. Seven of the remaining ten who dropped out during the rest of the study were members of the Consultation Group and three were members of the Control Group. Most of these dropouts occurred during Phase III. The fact that the Consultation Group had twice as many dropouts as the Control Group suggests a possible adverse effect of the consultation visits on continued participation of those laboratories.

The allocation of laboratories to groups is also presented in Table 1 according to hospital size. It can be seen that Criterion Group laboratories were located mainly in the larger hospitals, i.e., 25 out of 35 were in hospitals with 100 or more beds. Twenty-two out of 26 Consultation Group laboratories and 25 out of 29 Control Group laboratories were located in smaller hospitals containing fewer than 100 beds and generally situated in the rural areas of the state.

The level of participation increased with hospital size. Table 1 shows that the distribution of participating laboratories was highly representative of the laboratory population in the state as far as large laboratories were concerned. The smaller hospitals, however, were not as well represented, and a bias here, due chiefly to lack of response and partly to dropouts, is clearly indicated. Better participation from the smaller laboratories would have been desirable, since the additional information could have made the results obtained more representative of laboratory performance in hospitals of less than 50 beds. The poor response from hospitals of less than 50 beds could be attributed to increased laboratory workload caused by the

Control	6	15	4	2	2	29

survey samples. This increase would have had little impact, however, on the workload of larger laboratories.

Participation According to Phases

The number of laboratories reporting results according to determination and phase is presented in Table 2. Hemoglobin was the one determination on which all participants reported. Glucose and urea nitrogen were analyzed by most laboratories. The remaining determinations in decreasing frequency of reports were cholesterol, total protein, chloride, uric acid, and calcium. Since laboratories were requested to perform only those procedures which were normally done by them, the number of reports received on each determination seemed to reflect its popularity in hospitals throughout the state. Table 2 also shows that the response was quite uniform throughout the study for each determination. At the end of the study, 42 of the laboratories had reported on all 18 surveys before the deadline; 28 of these reported on all eight determinations, and 14 reported on seven out of the eight determinations.

Effect of Participation per se on Improvement of Laboratory Results

The target values for the various lots of lyophilized sera and hemoglobin solutions are shown in Table 3 according to the survey numbers in which they were distributed. The acceptable limits are also given for each determination. The acceptable results for each determination are presented in Tables 4-12; the unacceptable results are presented in Table 13.* The total "percent acceptable"

Continued

---

*Unacceptable results were listed according to determination and group in two categories: the number of results falling between the acceptable limits and ±20% of the target value, and the number of results which were greater than ±20% of the target value. The latter were considered extreme results.

results in terms of accuracy and precision for Phases I and III are given for each laboratory group. Improvement is indicated by a larger percentage of acceptable results in Phase III than in Phase I, thus giving a positive value in the column "Differences in Percentages (III - I)" for a particular group. Deterioration is indicated by a negative value.

To determine whether laboratory participation in an evaluation study resulted in improved accuracy and precision, the data obtained for the Criterion and Control Groups were each examined separately. In this analysis, the Criterion Group data reflected the effect of participation upon the upper one third of the laboratories, and the Control Group data represented the lower two thirds of the laboratories. The Consultation Group was omitted, since the aim here was to assess solely the effect of participation.

Although the tables show that the numbers of laboratories vary depending on the group or determination, the statistical analysis does take sample size into account. Only for true glucose were the number of laboratories for the Consultation and Control Groups undesirably small and the results perhaps inadequately determined. This situation occurred because most of the laboratories in these groups analyzed glucose by methods for total-reducing substances.

Significant improvement in accuracy was noted for the Criterion Group for calcium ($P = .002$) and cholesterol determined by "B" methods ($P = .03$). The Control Group demonstrated significantly improved accuracy in measuring urea nitrogen ($P = .01$) and uric acid ($P = .02$). [The Criterion Group improved accuracy for true glucose, calcium, uric acid, and cholesterol "A", and showed deterioration for total-reducing substances and chloride; while the Control Group showed no change for hemoglobin and total-reducing substances and improvement for calcium, chloride, total protein, and cholesterol "B". These changes did not approach significance.]

Precision for the Criterion Group showed significant improvement in the measurement of calcium ($P = .002$) and uric acid ($P = .05$) This group also showed significant deterioration in precision for total-reducing substances ($P = .04$). Those determinations performed more precisely in Phase III than in Phase I by the Control Group included calcium ($P = .004$), chloride ($P = .02$), urea nitrogen ($P = .02$), and total protein ($P = .08$). [The Criterion Group showed no change in determining hemoglobin; improvement for true glucose, urea nitrogen, and cholesterol "A"; and deterioration for chloride, total protein, and cholesterol "B", while the Control Group improved uric acid precision but showed deterioration for total reducing substances, hemoglobin, and cholesterol "B". None of these changes were significant.]

The results for the Criterion Group showed that precision was on a level comparable to that of accuracy with two exceptions — total protein and cholesterol. The group raised the level of accuracy of the cholesterol "A" methods to a par with precision in Phase III (accuracy went from 71% to 80% while precision remained about 82%). The comparable levels were maintained in both phases of the study. The Control Group, on the other hand, showed considerable variation in levels when accuracy and precision of each determination were compared. Like the Criterion Group, the Control Group demonstrated better precision than accuracy for total protein and cholesterol. In other determinations, the Control Group measured constituents with more accuracy than precision.

Although the Control Group was able to show some significant improvement in accuracy and precision, the over-all level of performance approached that of the Criterion Group in only one instance — accuracy of determining uric acid in Phase III. For some determinations, the level of performance was decidedly poor.

The fact that precision was considerably better than accuracy for total protein determination in both groups could be because many laboratories standardize their procedures with bovine albumin solutions. If these solutions have not been assayed by the Kjeldahl procedure, their use as standards

Continued

tends to over-estimate the true value of the protein content in the sample. Some variation in protein content as determined by the Kjeldahl procedure will also occur, depending on the type of catalyst used.*

The large difference in the numbers of acceptable results for the two classes of cholesterol methods is noteworthy. The "B" methods as a whole fall considerably short of the "A" methods in terms of both accuracy and reliability. The more time-consuming extraction procedures of Abell[11] or Schoenheimer and Sperry[12] consequently result in a high degree of accuracy and a comparable level of precision. As mentioned earlier, the "B" methods include so-called direct methods which have been shown to be adversely affected by high concentrations of serum bilirubin which in turn cause the cholesterol values to be falsely high, usually in a proportionate manner.

Effects of Consultation on Improvement of Laboratory Results

In the preceding section, the results obtained for the Criterion and Control Groups were derived from participation alone. Similarly the Consultation Group data stemmed from participation, but on the other hand, were also affected by the consultation visits given during Phase II. The *gross changes* (i.e., Phase III–Phase I differences in percentages) in accuracy and precision included both participation and consultation effects, while *net changes* measured the effect of consultation only. As defined earlier, net change was the change from Phase I to Phase III shown by the Consultation Group, corrected for the change shown by the Control Group. If the Consultation Group showed significant improvement over and above that of the Control Group, this could be interpreted as a net improvement due to consultation.

Grossly, the Consultation Group demonstrated significant improvement in accuracy for chloride ($P = .02$), hemoglobin ($P = .002$), urea nitrogen ($P = .001$), and cholesterol "B" ($P = .003$). Precision showed significant improvement for chloride ($P = .002$), urea nitrogen ($P = .01$), and hemoglobin ($P = .01$). [In terms of accuracy, the group showed no change in total-reducing substances and calcium and slight improvement in total protein and uric acid, while precision improved somewhat for total-reducing substances, total protein, uric acid, and cholesterol "B" and deteriorated for calcium. None of these changes were significant.]

Turning now to the question of consultation, it can be seen that intensive consultation was shown to be effective for only one determination. A significant net change was demonstrated for hemoglobin, since the Consultation Group showed marked improvement in both accuracy and precision and the Control Group did not. It is possible that the effect was thus seen for hemoglobin because this determination was the simplest to perform of all those included in the study. Therefore, corrections in methodology and technique were neither difficult for the consultant chemist to suggest nor for the laboratorian to comprehend.

The only other significant net change was that for calcium, namely, a net deterioration in precision. The explanation is not at hand; it is possible that this was related to the fact that the calcium determination was not emphasized as much as certain other determinations during the consultation visits.

Comments

When the study was initiated, it was hoped that the consultation would be given as intensively as possible and that each consultation laboratory would receive about one visit per month during the six-month consultation period. Due to a shortage of personnel during Phase II, each visited laboratory received only three visits. This may have contributed to the lack of sufficient evidence to support the premise that intensive consultation has a measurable beneficial effect.

Since the consultation and control laboratories were selected randomly from the lower-performing two thirds of the study sample, the two groups should have differed from each other only by chance, for each determination during Phase I. The tables show some differences between the two groups for Phase I, and these differences were significant for precision of measuring calcium, chloride, uric acid, and cholesterol. In retrospect, other factors (e.g., training of personnel, dropouts, turnover of personnel, hospital size) come to mind, which could have caused these differences but which were not apparent at that time. These findings suggest that a better design for selection of laboratory groups could have been employed which would have controlled some of the random variables more closely. Examples of such designs are the Matched Pair design and the Randomized Block design. While comparison of the two groups following randomization showed that they were similar in qualitative ways, one of these designs would have provided for a quantitative balancing of the two groups.

---

*Laboratories which do not have facilities for performing Kjeldahl analyses may be interested in knowing that standard protein solutions are available from the College of American Pathologists.

Awareness of a problem of nonscientific nature also occurred during the study. When a person associated with a state agency attempts to aid laboratories in improving their work, the efforts of the consultant take on the aura of a "policing" action. This effect can be overcome only by the establishment of good rapport between participant and consultant. Although this is not always an easy situation to establish, the absence of good rapport would most probably result in total ineffectiveness of consultation.

Relationship of Laboratory Results to Some Technical and Hospital Factors

One of the singularly important items which can be gleaned from the literature concerning laboratory evaluations is the consensus of opinion regarding the cause of poor performance. Most authors attribute inaccurate results to inadequately trained or inexperienced personnel, to lack of adequate supervision, and to the pressures of excessive workloads.[3,7,8,9,11,15] An attempt was made, therefore, to utilize the data obtained from individual laboratories for comparison of over-all performance with the following three factors: training of personnel, availability of a pathologist, and hospital size. The latter was indexed by two related variables — chemistry workload and bed category.

Information given on questionnaires completed by the participants was used to classify each of the ninety laboratories with respect to these four items, employing only results from the baseline period, Phase I, for the analysis. Data were pooled for each laboratory, regardless of determinations, to give a ratio score for accuracy and for precision of the total number of acceptable results over the total number of reports received.

Training of Personnel

Laboratories were classified according to the level of training of their personnel. If

Continued

one or more persons in the laboratory were registered by the American Society of Clinical Pathologists with or without a degree, were California state-licensed with or without a degree, or had a baccalaureate degree or higher from an accredited college in a scientific field, they were classified as "American Society of Clinical Pathologists registered or equivalent (ASCP)." Laboratories were classified as "Other" if their personnel had received their training from a commercial trade school, a laboratory assistant program, the Armed Forces, or on-the-job. The results for the two classifications in terms of accuracy and precision are given in Table 14, part 1a. The results clearly indicate that the ability to perform laboratory tests accurately and reliably is related to the level of training of the personnel. The differences between the performance of the well-trained personnel and that of the less-well-trained personnel were significant for both accuracy and precision ($P = << .001$ in each case).[46]

The results for the Consultation and Control Groups were also examined with respect to the level of training of personnel. The scores for individual laboratories in both groups for Phases I and III were used for this analysis. (See Table 14, part 1b.) The improvement seen in both groups for "American Society of Clinical Pathologists (ASCP)" was significant for both accuracy and precision ($P = .01$). The improved accuracy and precision for "Others" in the Consultation Group were significant ($P = .02$), while the changes for "Others" in the Control Group were not.

These results imply that well-trained personnel are capable of improving laboratory performance through participation in evaluation studies alone. On the other hand, participation alone apparently does not provide any benefit for less-well-trained personnel. Consultation appears to have a real effect in upgrading the level of performance of the less-well-trained people. Whether the newly attained level can be maintained without continued consultatory aid, particularly when turnover occurs, is quite doubtful.

Availability of a Pathologist

Laboratories were classified according to three categories for this analysis: "Yes" if the laboratory had the services of a resident pathologist or received daily visits from a pathologist, "Occasional" if the laboratory received periodic visits from a pathologist, and "No" if no pathologist visited the laboratory at any time. The results are given in Table 14, part 2. The differences among the three categories were significant for both

Continued

accuracy and precision ($P = <.001$ in each case via a Chi-square contingency table analysis with two degrees of freedom).[46] This indicates that supervision, as measured by the availability of a pathologist, is an important factor in determining the laboratory's ability to perform tests with a higher degree of accuracy and reliability.

Hospital Size: Chemistry Workload

Since laboratories throughout the state have various ways of recording work done, workload here was arrived at by summing the total number of hemoglobin determinations and the total number of chemical determinations on blood, plasma, or serum for the year 1962, and computing the average number per month. The workload figures were then grouped according to five categories and examined by means of regression analysis.[48] The results are given in Table 14, part 3a. The linear trends were significant for both accuracy and precision ($P = <.0005$ in each case).

Hospital Size: Bed Category

Laboratories had previously been classified according to hospital size as indexed by bed category for purposes of illustrating level of participation. Performance as it relates to bed category was also measured by regression analysis.[48] The results are given in Table 14, part 3b. The linear trends for both accuracy and precision were significant ($P = <.0005$ in each case).

Results for the two indices of hospital size indicate that the level of performance increases with the size of the hospital. This could be related to the greater likelihood of finding better-trained personnel in the laboratories of larger hospitals. Increased accuracy and precision also go hand-in-hand with carrying out laboratory tests at greater frequency. This is reflected in the larger workload categories.

Comments

Even though the relative importance of each factor could not be determined, it is interesting to note that laboratories showing top performance in each factor-comparison were, in general, the same laboratories. The smaller hospital laboratories, which were performing on the lowest level, also gave the poorest cooperation. These laboratories are staffed by personnel trained in commercial schools more often than larger laboratories, and as a rule are not supervised by pathologists.

Summary and Conclusions

An evaluation study in clinical chemistry involving 18 separate surveys was conducted by the Minnesota Department of Health in hospitals throughout the state. Ninety laboratories completed the study.

The purpose of the study was to determine:

1. Whether participation in an evaluative study over a period of time would cause improvement in laboratory results, and

2. Whether intensive consultation would be an effective means of upgrading laboratory results.

Laboratories were divided into three groups. The Criterion Group included the top-performing one third of the laboratories. The remaining two thirds were assigned to the Consultation or the Control Group. Accuracy and precision of eight determinations — glucose, calcium, chloride, hemoglobin, urea nitrogen, total protein, uric acid, and cholesterol — were measured for each group in each survey.

The Criterion and Control Groups were used to study participation. The results showed that participation in evaluation studies could bring about improved laboratory results for some determinations. The Control Group, however, did not approach the level of performance of the Criterion Group.

Intensive consultation was studied with the Consultation and Control Groups. Results indicated that consultation visits given to laboratories in the Consultation Group were effective in upgrading only one determination significantly, namely hemoglobin.

Laboratories were also rated according to three factors affecting laboratory results: level of training of personnel, availability of a pathologist, and hospital size (indexed by chemistry workload and bed category). Total

Continued

performance scores for each laboratory were compared with each factor. The results showed that:

1. Laboratories employing well-trained technologists demonstrate a higher level of accuracy and precision than those employing less-well-trained laboratorians.

2. Well-trained technologists are capable of significantly improving laboratory performance by participating in evaluation studies, while less-well-trained laboratorians gain little or no benefit from participation.

3. Less-well-trained personnel are able to improve performance significantly when given intensive consultation.

4. Laboratories supervised by pathologists perform tests more accurately and precisely than those not supervised by pathologists.

5. The level of performance of a laboratory increases as bed category and workload increase.

In terms of the expense involved, the benefit gained from intensive consultation is questionable — at least on the short-term basis available in this study. The positive effect of consultation found for one determination does imply that this means of improving laboratory performance should be reexamined. In addition, the possible need for a continuing program to maintain the improvement in performance of the less-well-trained personnel should be studied. Future studies might well be devoted to discovering the most effective and economical methods for improving laboratory performance.

CASANOVA, the libertine, was told by a surgeon that he was indebted to him for his present comforts, and when he inquired why, the surgeon stated: "In this way, captain. You had a connection with Don Jerome's housekeeper, and you left her, when you went away, a certain souvenir which she communicated to a certain friend of hers, who, in perfect good faith, made a present of it to his wife. This lady did not wish, I suppose, to be selfish, and she gave the souvenir to a libertine, who in his turn was so generous with it that, in less than a month, I had about fifty clients."*

Perinatal Mortality Study

Prolonged Labor—Uterine Inertia *

Case Report

This was the first pregnancy of this twenty-two-year-old mother. Prenatal care began during the second lunar month, and she had no illness during the pregnancy. At 36 weeks of gestation she entered the hospital emergency room because of periodic abdominal pains for two days and now occurring every fifteen minutes. A diagnosis of very early labor was made, and the patient was discharged, but she returned two hours later, at which time both the patient and her husband were very anxious.

Physical Findings

Examination on the return admission revealed the cervix to be 1-2 cm. dilated and 75% effaced. The periodic abdominal pains continued, but of poor quality, and 12 hours following admission the cervix was 4-5 cm. dilated. The fetal heart tones were normal. Pelvimetry on the day of admission showed a normal pelvis. Twenty-two hours following admission a vaginal examination revealed the cervix to be thin and 4-5 cm. dilated.

Therapy

The mother then received 100 mgm. intramuscular Librium which slowed the labor and relaxed her. Forty-four hours following admission the membranes ruptured and she was started on penicillin and streptomycin therapy.

Uterine Inertia

Three days after admission labor finally stopped altogether. A urinalysis done three days following admission showed 2 to 3 plus WBC, no albumin, no sugar, no casts or bacteria. No urine culture was done, but the physician started the mother on Gantrisan therapy for four days. Four days after admission the mother was moved to a nonmaternity floor, and the penicillin-streptomycin therapy was changed to Achromycin, 1 capsule four times daily. Five days following admission the mother had a yellow vaginal discharge. No smear or culture was done on the discharge. A vaginal examination done on the fifth day revealed the cervix to be 9 cm. dilated and station plus one.

Stimulating Labor

The mother was then given Tocosamine lcc. I.M., which caused no change. Nine hours after the Tocosamine, she had irregular contractions three to ten minutes apart. The cervix remained 9 cm. dilated and station plus one. The mother was then given intravenous pitocin drip (½ ampoule in 500 cc. glucose in water); after four hours of pitocin drip the contractions were four to 26 minutes apart and of poor quality. The position of the infant was occiput posterior, and the fetal heart tones were 130 to 160 per minute. It was now the sixth day after admission.

Low Forceps Delivery

The physician then used low forceps to deliver the occiput posterior infant under pudendal and paracervical block anesthesia. The fetal heart rate was 160 per minute one hour before delivery, 108 per minute one-half hour before delivery. After delivery the infant took only one or two gasps. Positive pressure oxygen and intubation were used on the infant to no avail, and it expired in less than one minute. No obstetric consultation was obtained at any time.

Autopsy Findings

Autopsy on the 6-lb. male infant showed the abdominal cavity to be filled with blood, estimated at approximately 60 cc. in amount. The capsule of the liver was torn in two places over the costal margin. There were subcapsular hematomas measuring up to 1 cm. in diameter adjacent to the liver capsule tears. Microscopic examination of the liver in the area of the capsule tears showed some early degenerative changes in the liver cells and some areas of hemorrhage into the parenchyma. Also, small hematomas were seen beneath the liver capsule.

---

*Ramsey County Perinatal Mortality Study Committee.

The lungs did not float in water, and microscopic examination of them showed most of the alveoli to be collapsed. The remainder of the autopsy, including the brain revealed no areas of hemorrhage or abnormality.

The pathologic diagnosis was hemoperitoneum with laceration of the liver capsule and subcapsular hematomas.

Comment

The Ramsey County Perinatal Mortality Study Committee criticizes the care that the mother received as follows:

Unjustifiable Delay

A primary uterine inertia was not stimulated when no progress had been made in the twelve-hour and the twenty-second-hour examination. Stimulation, not relaxation (Librium) was indicated. Had *stimulation, amniotomy* and/ or Tocosamine or Pitocin failed, *the patient should have been sectioned* on the basis of "failed labor." The remainder of the management was indefensible, including the apparently traumatic delivery which was apparently the direct cause of perinatal mortality.

Plants Yield Tumor-Inhibiting Compounds

Podophyllotoxin has been obtained from *Juniperus virginiana* L. by S. Morris Kupchan, Jane Hemingway, and John Knox. An alcoholic extract of the leaves and twigs of the plant from Maryland was found to have inhibitory activity against Sarcoma 180 in mice and *in vitro* against human carcinoma of the nasopharynx carried in cell culture. (KB).

March '65, American Pharmaceutical Association, 2215 Constitution Avenue, N. W., Washington, D. C. 20037.

Post Hoc, Ergo Propter Hoc

The treatment of typhoid fever throughout the years has been variable and very interesting. An outstanding product used for a long period was antimony, which has no value in the treatment of the disease, but because it was given to Louis XIV and he seemed to improve following its administration, it became a favorite for years. Louis had been very ill with typhoid for a long time and showed no improvement with the usual concoctions of gold leaf suspended in wine, pearls dissolved in vinegar, and frequent poulticing. He was purged and bled, bled and purged and at last in desperation, his physician tried antimony. Louis was due to either die or get well and because the latter was in order, the antimony was given the credit.

Life Insurance Dividends

Since the average doctor carries approximately $70,000 worth of life insurance, the disposal of the dividends which his policies earn should be an important matter to him.

With regard to dividends, participating life insurance contracts usually provide the policy holder a choice among four options. (1) Under the "cash" option, dividends will be paid to him annually in cash. (2) The "premium' option provides that the dividends will be used annually as partial satisfaction of premium due. (3) The "paid-up insurance" option provides for the use of annual dividends for the purchase of paid-up additions to the life insurance policy. (4) The "interest" option provides for the deposit of dividends with the company to accumulate at interest.

In general, options No. 1 and No. 4 have little value for the doctor who is in the process of building up his life insurance program. Option No. 1 should be chosen only by the man whose policies are already paid up and who has no need for additional insurance. Option No. 4 lost its attractiveness when yields from other sorts of investments (even savings accounts in commercial banks) began to surpass the insurance companies' 2 or 2½ per cent, and besides, with most low-net-cost companies, the paid-up additions available under option No. 3 acquire a cash value which will equal or exceed the accumulation of dividends and interest over a period of years.

In general, option No. 4 would be worthy of consideration only on contracts permitting the conversion of accumulated dividends and interest to paid-up insurance at any time. Such a privilege is relatively rare today.

It is our feeling that options No. 2 and No. 3 are most worthy of consideration by the average policyholder. Option No. 2 should be elected by the young doctor who is building up a large insurance program and wants maximum protection. Obviously, he can buy much more insurance by paying only the net premium (premium less dividend), than by using dividends otherwise. Later, if his financial position improves or if he becomes uninsurable, he can change his election to option No. 3 (paid-up insurance) if he wishes.

Option No. 3 is generally best for a doctor between 40 and 50 years of age who does not have as much insurance as he should have or would like, and it is also quite valuable to the man who has become uninsurable. Men in these situations can elect to have their dividends purchase paid-up additions which will increase their protection and also maintain a cash value equal to, or slightly greater than, the sum dividends and interest would have provided them if they had been left on deposit. Thus, such men would have maximum protection, but still would retain a cash reserve for retirement or for emergency use.

What about doctors who elected years ago to leave their dividends on deposit? Such a man has a sizeable accumulation drawing 2 or 3 per cent taxable interest. His individual situation should be reviewed and probably his dividend option changed. If he needs protection through additional insurance, a paid-up insurance option should be taken on future dividends and — to the extent possible — on accumulated dividends.

To the extent that paid-up additions are prohibited on the accumulation, it is our feeling that these dividends can be withdrawn and profitably invested elsewhere. That course of action should also be chosen by the man whose insurance needs are declining. He can withdraw his dividends and reinvest them at a higher return.

Before making a decision on a matter of this sort, one should review his needs and his coverage with a competent insurance agent or analyst. He must consider his over-all financial position in relation to the options that are available under the particular contracts he owns.

If you have a dividend problem, you should consult a qualified advisor at once.

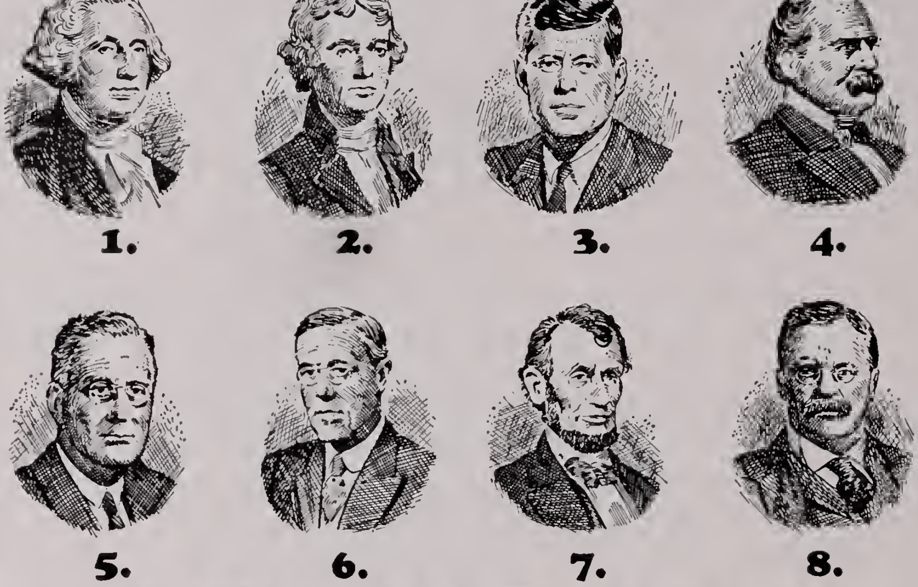
The Renville-Redwood County Medical Society wishes to announce the winners in Renville County of the 1965 Association of American Physicians and Surgeons 19th Annual National Essay Contest for high school students. First place goes to Karen Halliday of Olivia; second place prize goes to Jim O'Malley, Olivia, and third place prize to Vickie Wiersma of Olivia.



For this idea, thanks to the Bank of America, where you also meet nice people.

You meet the nicest people when you buy U. S. Savings Bonds

This gallery of Presidents is available in steel engravings from the U. S. Government. They are, of course, the Presidents who appear on Series E Savings Bonds—one for each denomination.

All you have to do to complete this series of great men who led our country in the paths of freedom is to buy one each of the eight kinds of Series E Bonds.

While you are enjoying your collection, your Bonds will be growing at an average rate of 3¾% to maturity. At the same time Uncle Sam will be using your Bond dollars to help strengthen freedom everywhere.

Start meeting some of these nice people soon, and see if you don't get a nice red, white, and blue feeling.

Who they are and where you find them: 1. George Washington on the $25 Bond. 2. Thomas Jefferson, the $50 Bond. 3. John Kennedy, $75 Bond. 4. Grover Cleveland, $100 Bond. 5. Franklin Roosevelt, $200 Bond. 6. Woodrow Wilson, $500 Bond. 7. Abraham Lincoln, $1000 Bond. 8. Theodore Roosevelt, $10,000 Bond.

In Memoriam

This world is the land of the dying; the next is the land of the living.
— Tyron Edwards

ALVA E. HOLMES, M.D.

Dr. Alva E. Holmes, 86, Rush City physician, died February 26. He was born in Virginia City, Nevada, and received his degree in medicine from the Kentucky School of Medicine in Louisville, Kentucky.

He was a member of the American Medical Association and East Central Medical Society and a 50 Club member of the Minnesota State Medical Association.

He is survived by a sister in Culver City, California.

JOHN A. O'HANLON, M.D.

Dr. John A. O'Hanlon, 59, Minneapolis physician, died May 14th. A native of Minneapolis, Dr. O'Hanlon attended St. Thomas Academy and College prior to attending Marquette University Medical School, Milwaukee. He had been in private practice since 1949 and was chief medical officer of the Minneapolis Postoffice.

He was a member of the Hennepin County Medical Society, Minnesota State Medical Association, and American Medical Association.

He is survived by his wife, a daughter, and two sons.

HENRY C. OTTO, M.D.

Dr. Henry C. Otto, 79, resident of the Frazee-Vergas area for the past fifty-six years, died, April 27th. He was born on a farm in rural Nicollet county, but received his medical degree from the University of Louisville in Louisville, Kentucky.

Dr. Otto was a member of the Masonic Lodge No. 241 AF and AM, Scottish Rites bodies, Clay-Becker Medical Society, Academy of General Practitioners, American Medical Association, and life and 50 Club member of the Minnesota State Medical Association. He had been a member of the staff of St. Mary's hospital.

He is survived by his wife, a son and a daughter.

ROLF HOVDE, M.D.

Dr. Rolf Hovde, 72, physician and surgeon in Winthrop for forty-six years, died at his home, April 10th. He was born in Brookings, South Dakota, and moved with his family to Duluth when he was eight years old. He received his medical degree from the University of Minnesota and interned at the Hennepin County General Hospital in Minneapolis.

Dr. Hovde was a member of the American Medical Association, Southern Medical Association, Brown County Medical Society and Minnesota State Medical Association. He also served on staffs at Union and Loretto hospitals in New Ulm, Glencoe, Arlington and Gaylord. Activity in Masonic groups led to his attaining the highest office of the Knights Templar in Minnesota, that of Grand Commander.

He is survived by his wife, three sons and a daughter.

THOMAS E. FLINN, M.D.

Dr. Thomas E. Flinn, 80, Redwood Falls physician, died April 8, at the Redwood Falls hospital. He was born in Redwood Falls and graduated from the Rush Medical College, Chicago. He began the practice of medicine in Redwood Falls in 1911 and remained there until his retirement in 1946.

He was a member of the American Medical Association, Renville-Redwood Medical Society and a 50 Club and life member of the Minnesota State Medical Association.

He is survived by his wife, one daughter and two sons, one of whom is Dr. John H. Flinn of Rochester. Another son, Dr. William C. Flinn, was killed in an accident in France in 1945.

This hat does things for you

It represents the forest fire prevention campaign serving every American business that depends on wood or wood products — *your* business, very likely. It's been pretty successful, too. Since this campaign began in 1942, there have been over 272 thousand acres that did *not* burn, more than 1 million fires that did *not* happen, and 10.1 billion dollars worth of damage that did *not* occur. But Smokey's job will never end, and he needs your help. *You* can wear that hat, too, by urging your employes and the people in the communities in which you do business to be extra careful with fire — *every fire.*

remember-only you can prevent forest fires

Material for posting on your bulletin board available from your State Conservation Department or the nearest office of the U. S. Forest Service.

History of Medicine
IN WRIGHT COUNTY

JOHN J. CATLIN, M.D.
Buffalo, Minnesota

ROBERT ROSENTHAL, M.D.
St. Paul, Minnesota

Editors Note: Article continued from June 1965 issue of Minnesota Medicine.

Rufus L. Thurston, a homeopath, was at South Haven for a short time. He was licensed in Minnesota as a homeopath August 23, 1884. He was a graduate of the Hahnemann Medical College of Chicago in 1882. In 1890 he is listed in Minneapolis, from 1895 through 1909 in Boston, Mass.

Gilbert H. Tollington, practiced in Clearwater from about 1890 through 1898. He was one of four physicians there in 1890 when Clearwater had a population of about 400; while in 1893 and 1896 only he and Dr. I. L. Edmunds are listed there, when the population was below 300. All in all it seems that he was in Clearwater about ten years as he left that town before the turn of the century. Dr. Ira Leslie Edmunds was one of the physicians in Clearwater at that period and a St. Cloud newspaper item of July, 1896 mentions that Drs. Tollington, Edmunds and Ridgway did surgery together at the St. Raphael's Hospital in St. Cloud. During the first decade after the turn of the century he practiced in Minneapolis.

He was a graduate of the College of Physicians and Surgeons, Chicago in 1885 and was licensed in Minnesota April 28, 1887. He was the son of Thomas and Sarah Tollington. His sister, Ann Jane, married Dr. I. L. Edmunds.

A "**Dr. Trow** of Cokato" opened his large residence for use as an emergency hotel after the regular hotel burned down. Nothing more could be learned about him; it could not even be ascertained that he actually was a physician.

Sidney R. Wakefield, a homeopath, came to Minnesota in 1866 and settled in Monticello. He was born in Trumbull County, Ohio April 18, 1822 and graduated from Willoughby Medical College, Willoughby, Ohio in 1846. During the Civil War he served as assistant surgeon in the 71st Ohio Volunteer Infantry Regiment and came to Minnesota after the war. He was a founder and a signer of the Articles of the Minnesota State Homeopathic Institute when it met in 1867 at the Globe Hotel in St. Paul.

In 1871 Dr. Wakefield advertised "special attention paid to surgery of all kinds, also to chronic diseases, pulmonary and throat affections, and all their diseases and maladies."* At that time his office was located over T. G. Mealey's Dry goods and grocery store. It seems he moved away again as we learn early in 1881 that Dr. Wakefield's "goods and chattles have arrived. The doctor's family is expected daily." In May his family had joined him.

He was now one of three doctors in Monticello, the others being Drs. Gibbs and Smith. By June he had rented a house and was ready to start

---

*The Northern Statesman (Wright County) February 4th, 1871.

Continued

practice.* He may have done coroner's services as in November 1884 his claim of $13.40 for an inquest was approved by the county.

He was licensed in Minnesota December 31, 1883. He was listed as practicing in Monticello through 1900 and apparently had an extensive rural practice. He was a charter member of the Wright County Medical Society when it reorganized in 1894 under this new name. The organizational meeting was held August 1 in the parlor of the American House at Buffalo, Dr. Wakefield calling the meeting to order. He was elected vice president. Dr. Wakefield died December 13, 1916 in the home of his son in Creswell, Oregon, of "senile debility" at the age of almost ninety-five.**

He probably was a relative of Dr. Kee Wakefield of Hutchinson, McLeod County, who practiced there in the 1880's and visited Monticello in 1881.

Clement A. Westholter, practiced in St. Michael from 1896 through 1900. While there he built a large house in the country toward Albertville. He tried to establish a "Water Cure" and it seems he was more interested in establishing and running a cure for chronic diseases than to have a regular practice. St. Michael apparently attracted him because of its German community, but he was not able to succeed there as a physician.

Dr. Westholter was born in Hamm, Westphalia, Germany and received his medical education at the University of Paderborn (1878). He practiced in Gottingen for three years before coming to the United States in 1882. Here he practiced in Tatopolis, Illinois and Indianapolis, Indiana. He was licensed in Minnesota April 14, 1896 and practiced in this state in St. Michael, in Buckman, Morrison County, and Albany, Stearns County. He died in Albany in 1921. He was married and had twelve children.

Jarid D. Wheelock, was a very early pioneer physician of Wright County. He came to Clearwater in 1855 as the first physician to settle in Wright County. He was licensed in Minnesota by exemption (under the "years of practice" section of the act) November 28, 1883.

In the early 1870's he was associated with Dr. Collins and the card of "Wheelock and Collins," appeared for half a year in the *Wright County Times* of 1875. In Clearwater he is listed as late as 1890 (but no longer in 1893). In 1890 Clearwater had a population of about 400 and there were four physicians (Drs. Edmunds, Munger, and Tollington besides Dr. Wheelock).

Dr. Wheelock was born in Montpellier, Vermont September 28, 1820.† He studied medicine at the College of Woodstock, Vermont. He died September 11, 1891 at the age of seventy-three.‡ A St. Cloud newspaper carrying the death notice, states that twenty-five or thirty years ago he was a resident of St. Cloud (this must have been in the 1860's)§ and he moved from there to Clearwater. It also recalls that he was a highly esteemed and skillful physician. Dr. Wheelock was also interested in farming.

**James Eckman, "Homeopathic and Eclectic Medicine in Minnesota," Minnesota Medicine, November, 1941, p. 971.

†Upham and Dunlap "Minnesota Biographies, 1655-1912."

‡If his birthdate is correct he was only 71 at the time of his death.

§It seems he was in St. Cloud in 1865, and then was in partnership with Dr. M. C. Talman.

Conscience is the still small voice that makes you feel even smaller.

— Herbert Prochnow

Physician's Diary

In poverty and other misfortunes of life, true friends are a sure refuge — The young they keep out of mischief; to the old they are a comfort and aid in their weakness, and those in the prime of life they incite to noble deeds. — Aristotle

Dr. Fred D. Roth was elected president of the Mankato Clinic, Ltd. recently. Other officers are: **Dr. John J. Heimark**, vice president; **Dr. Chester E. Thiem**, secretary, and **Dr. A. A. Schmitz**, treasurer.

* * *

Dr. J. C. Swan, Mayo Clinic heart specialist and director of St. Mary's hospital cardiology laboratory, is to become chief of cardiology at the new Cedars Sinai Medical center in Los Angeles.

* * *

Dr. J. E. Nord and **Dr. Phillip Parker** of Staples were honored at an appreciation dinner recently by the people of Staples. **Dr. Nord** is leaving Staples and will relocate in Ada.

* * *

Dr. O. H. Beahrs, head of a section of surgery in the Mayo Clinic, was elected president of the Society of Head and Neck Surgeons at the annual meeting of that organization at San Juan, Puerto Rico.

* * *

Dr. James N. Kvale has opened up a practice in Atwater.

* * *

Dr. G. E. Lee has been reappointed chief of the medical staff of Glenwood Community hospital at its annual meeting. **Dr. B. A. Kolp** was appointed vice president and **Dr. R. R. Frear** of Brooten, secretary-treasurer.

* * *

Dr. Gordon Seagrave, the famed "Burma surgeon" died at his Namkham hospital last March. MINNESOTA MEDICINE published an article on **Dr. Seagrave** and his tremendous work in Volume 46:595, 1963.

* * *

Drs. A. L. Vadheim and **F. N. Thomsen** were recently made honorary members of the medical staff of the A. L. Vadheim Memorial Hospital in Lake Benton.

* * *

Dr. John C. Duffy, a Fellow at the Mayo Clinic, Rochester, Minnesota won the 1965 Grand Award of $500 in the "In My Opinion" competition cosponsored by the Student American Medical Association and Wyeth Laboratories at Radnor, Pennsylvania.

* * *

Dr. Robert V. Hodapp of Willmar has been appointed to the advisory committee on health and physical education of the Minnesota State Department of Education.

* * *

Dr. Jan Tillisch, Mayo Clinic section head, who has been ill in Athens, Greece, has returned to Rochester and is recovering satisfactorily.

* * *

Dr. Douglas J. Coy, Grand Rapids Clinic, and **Dr. Robert P. Balderson**, Itasca Memorial hospital, addressed the Range Medical Society at its April meeting. Their subject was "Non-malignant Diffuse Thyroid Disease."

* * *

Minnesota has more volunteer-physicians who have spent time on the HOPE ship than any other state except a few of the larger ones like New York. Fifteen have gone from Minnesota, twelve from the Twin Cities. Also, a bigger response to an appeal for funds comes in each year from Minnesota.

* * *

Dr. Walter H. Fink was honored at a dinner given for him by fellow members of the Minneapolis Ophthalmological Society at the Minneapolis Club on April 20th. **Dr. Fink**, who recently retired after forty years practice of ophthalmology in Minneapolis, was the founder of the Society.

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, N.Y.

to assure pain relief in relaxant therapy

In painful skeletal muscle spasm, relief of pain does not always follow relaxant therapy, as in the presence of—

Provocative pain, when muscle spasm is triggered by some underlying musculoskeletal defect.

Residual pain, when relaxation of severe spasticity leaves a degree of myalgia that continues to cause discomfort.

Severe pain, when the degree of pain is such as to cause persistence of symptoms in spite of relaxant therapy.

Emotionally aggravated pain, when anxiety or agitation creates tensions that undermine the efficacy of relaxant medication.

For decisive relief—lest persistent pain overshadow the benefits of relaxant therapy—many physicians prescribe Robaxisal or Robaxisal-PH.

Synergistic double action

In Robaxisal the potent action of the well-recognized skeletal muscle relaxant Robaxin (methocarbamol)[1,2,3,4,5,6,8] is accompanied by the time-tested analgesia of aspirin. This "rational therapeutic combination"[7] proves especially effective, since clinical studies have attested that the concurrent ingestion of methocarbamol and aspirin produces higher salicylate levels than equivalent doses of aspirin alone[7]...with "gratifying relief" of pain as well as spasm.[7]

INDICATIONS: Strains and sprains, painful disorders of the back, "whiplash" injury, myositis, pain and spasm associated with arthritis, torticollis, and headache associated with muscular tension.

CONTRAINDICATIONS: Hypersensitivity to any one of the components.

SIDE EFFECTS: Lightheadedness, slight drowsiness, dizziness and nausea may occur rarely in patients with unusual sensitivity to drugs, but usually disappear on reduction of dosage.

Supplementary sedation

In Robaxisal-PH, the relaxant Robaxin is combined with the analgesic-sedative ingredients of the popular Phenaphen formula, for use when emotional tensions aggravate the spasm-pain syndrome. Anxiety is eased by the phenobarbital component, which also enhances analgesic effects; and any tendency to gastric upset is minimized by hyoscyamine in the formulation.

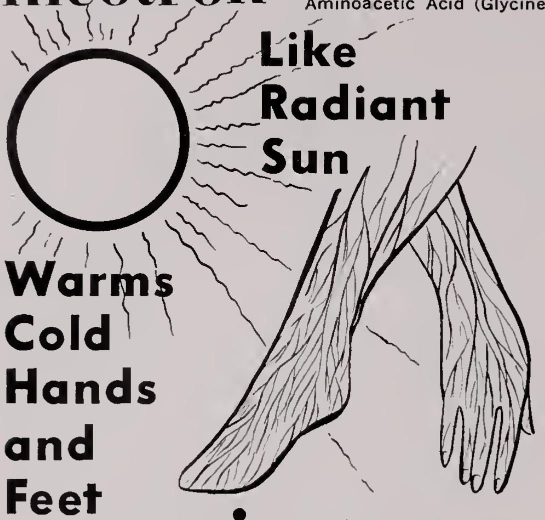
nicotron™ Nicotinic Acid and Aminoacetic Acid (Glycine)



Like Radiant Sun
Warms Cold Hands and Feet

nicotron™
NICOTINIC ACID +
AMINOACETIC ACID (Glycine)

increases and sustains
peripheral blood flow (1-2)

INDICATIONS: Poor circulation causing cold hands and feet or pain on walking. For the more serious peripheral vascular disturbances such as . . . Raynaud's Disease, Meniere's Syndrome, intermittent claudication, diabetes, post-phlebitis syndrome, leg ulcers due to venostasis and chronic thrombophlebitis.

DOSAGE: 1 or 2 teaspoonfuls or 1 or 2 tablets 3 times a day before meals. The feeling of warmth and tingling of the skin is a desirable effect. If this reaction is too pronounced reduce dosage.

CONTRAINDICATIONS: There are no known contraindications.

SUPPLIED: 8 oz. bottles and bottles of 100 chew-tabs.

FORMULA: Each teaspoonful (5ml.) elixir or each chew-tab contains:
Nicotinic Acid . . . . 75 mg.
Aminoacetic Acid (Glycine) . . . 750 mg.

Hygroton®
brand of chlorthalidone

the long-acting diuretic

Indications: Many types of edema involving retention of salt and water.
Contraindications: Hypersensitivity and most cases of severe renal or hepatic disease.
Precautions: Reduce dosage of concomitant antihypertensive agents by at least one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take special care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.
Side Effects: Agranulocytosis, constipation, dizziness, dysuria, headache, hyperglycemia, hyperuricemia, impotence, leukopenia, muscle cramps, nausea, postural hypotension, purpura, thrombocytopenia, transient myopia, urticaria, vomiting and weakness.
Average Dosage: One tablet (100 mg.) daily with breakfast.
Availability: Tablets of 100 mg. in bottles of 100 and 1000.
For full details, see the complete prescribing information.

*Dorhout Mees, E.J., and Geyskes, G.G.: Acta med. scandinav. 175:703,1964.

Photos: A 59-year-old woman with hypertensive cardiovascular disease and edema resistant to low-salt diet and bed rest. The patient lost 8½ lbs. in one week with a single tablet daily of Hygroton, brand of chlorthalidone.

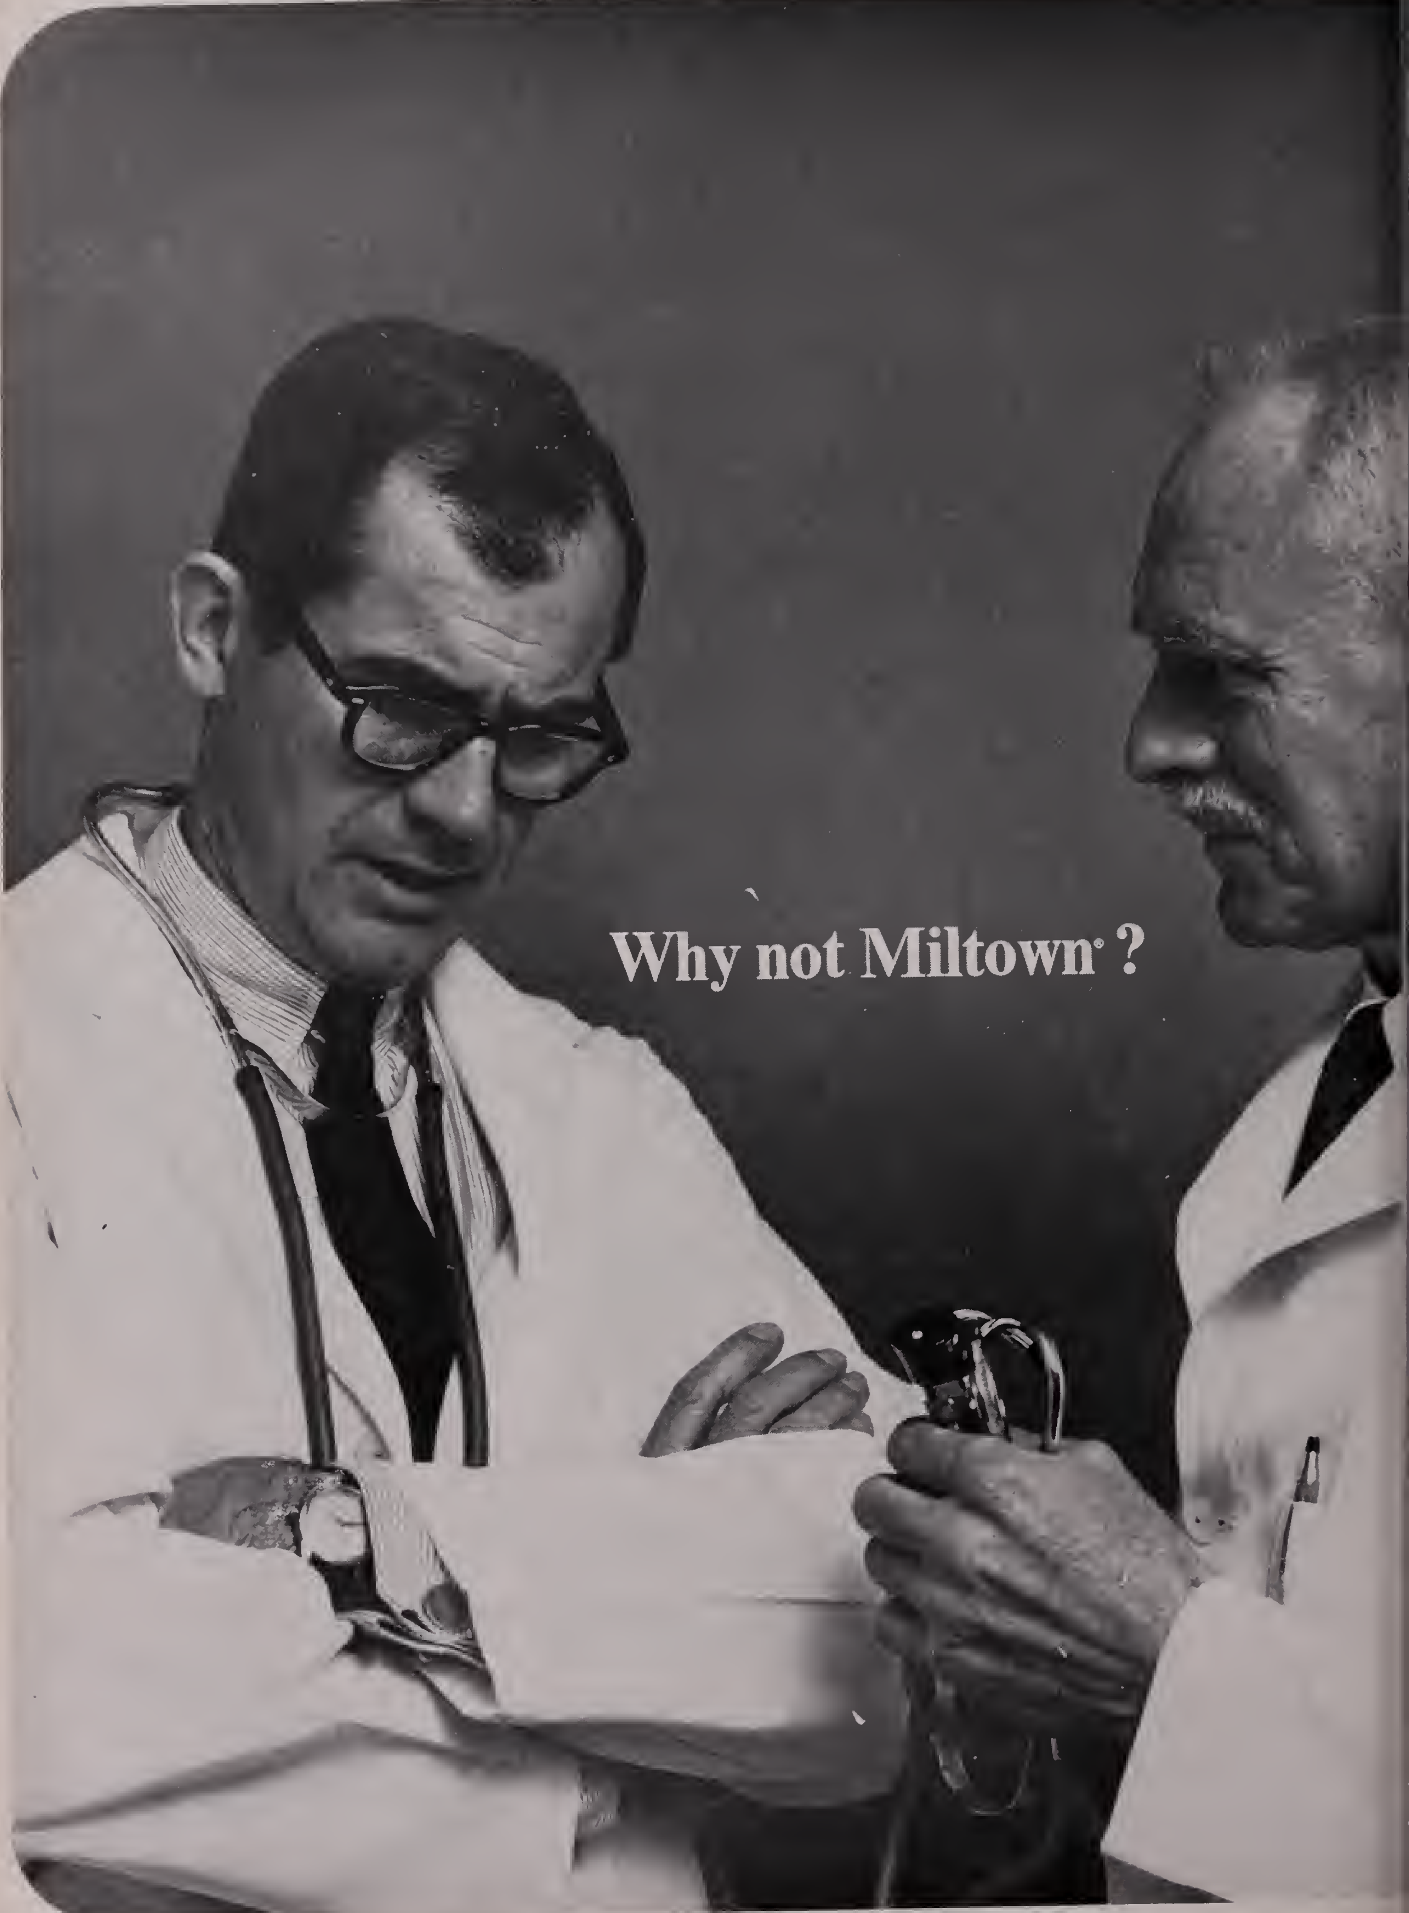
good riddance

Hygroton, brand of chlorthalidone, gets rid of edema efficiently. Your edematous patients will generally need far fewer tablets than with most diuretics. And they'll generally save more on prescription costs. One tablet a day is a popular dosage. So is one tablet every other day. You may even find half a tablet three times a week does the job. No other diuretic works as long. And none has as much natruretic activity per tablet.* For good riddance of edema with the least number of tablets, prescribe Hygroton, brand of chlorthalidone.

Hygroton® brand of chlorthalidone **Geigy**



Why not Miltown® ?

There are few "nots" in Miltown therapy

- **Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.**
- **The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.**

Indications: 'Miltown' (meprobamate) is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, 'Miltown' fosters normal sleep through both its anti-anxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of pre-existing symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: In two strengths: 400 mg. scored tablets and 200 mg. coated tablets.

Before prescribing, consult package circular.

NTZ Nasal Spray relieves hay fever symptoms on contact

Fast symptomatic relief from seasonal hay fever comes in the convenient NTz Nasal Spray bottle. Two sprays quickly relieve itching and decongest the nasal membranes on contact. The first spray of NTz shrinks the turbinates, helps restore normal nasal ventilation and breathing. After a few minutes a second spray enhances sinus ventilation and drainage.

NTz Nasal Spray reduces excessive rhinorrhea without unpleasant dryness. It is well tolerated by delicate respiratory tissues. NTz also provides relief in head colds, perennial rhinitis and sinusitis.

NTz's carefully balanced formula relieves three ways: with a decongestant, a topical antihistamine, and an antiseptic wetting agent.

Neo-Synephrine® HCl 0.5%, a decongestant of unexcelled efficacy to shrink nasal membranes.

Thenfadil® HCl 0.1%, a topical antihistamine to help relieve itching.

Zephiran® Cl 1:5000, an antiseptic wetting agent to promote the rapid spread of components to less accessible nasal areas.

NTz is supplied in leakproof, pocket-size, spray bottles of 20 ml. and in bottles of 30 ml. with dropper.

Winthrop Laboratories, New York, N. Y. 10016

NTZ, Neo-Synephrine (brand of phenylephrine), Thenfadil (brand of thenyldiamine), and Zephiran (brand of benzalkonium, as chloride, refined), trademarks reg. U.S. Pat. Off.

GENERAL INFORMATION

Authors

Manuscripts for consideration in Minnesota Medicine should be addressed to Office of Publication, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102. Papers should be typed double spaced on white paper with a wide margin. The first page should list the title, the name of the author (or authors), degree, and any institutional or other credits. Pages should be numbered consecutively. Tables should be typed and numbered and should have a brief descriptive caption.

Bibliographical references should be limited to twelve and should be typed in conformity to the method used by the Index Medicus. They should be numbered consecutively in the order in which they first appear in the text. Book references should give the name of the author, title, edition number, publisher, and the year.

Illustrations (photographs, tables, and graphs) should be submitted on separate sheets of paper and not combined in the text. Instructions for combining photographs are acceptable.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association of any of its constituents.

Advertisers and Subscribers

Display advertising rates on request. Classified advertising rates appear on classified page.

Annual Subscription—$6.50. Single copies—$1.00. Foreign and Canadian—$7.50.

Communications concerning advertising and subscriptions should be addressed to Minnesota Medicine, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102. Telephone CApital 4-5738.

Copyright and Post Office Entry

President's Letter

This letter is being written at the close of another successful state medical meeting, and there are many to whom we owe our thanks. First, I would mention the Committee on Scientific Assembly which began its meetings last August and arranged an outstanding program. It was stimulating to see so many physicians at all the sessions and especially to note the interest in the panels emphasizing the psychologic and religious implications of medical practice. To all of the speakers, discussion leaders, and exhibitors we are grateful. Likewise, the many committees on local arrangements are to be congratulated, and we can never overlook the good work of the state office staff. For the benefit of the members of the various committees which met for breakfast discussions, I am recommending that special attention be paid in the future to obtaining facilities which will be more private and quiet for their deliberations which are such an important part of our work. A two-day meeting necessitates some condensation of the committee program.

In the House of Delegates there were two actions which I consider of great significance. One was the overwhelming vote to discard any expression of non-participation in proposed government plans for the care of patients over 65. This establishes our policy for the present and in no way obviates continued opposition to government control, while adhering at the same time, to principles involved in caring for all, regardless of need. The other significant event was the agreement by Minnesota Blue Shield to implement the major proposals of the Ad Hoc Committee to study that organization, which were approved by the House. With a closer working relationship assured, we look forward to a new era of successful operation of Blue Shield. An important feature is the agreement to promote the usual and customary fee as a basis for payment to the physician. If our experience with Medicare for servicemens' dependents is accurate, we can predict that Minnesota physicians will be cooperative in fulfilling the spirit of this concept. The success of the "usual fee" plan will require continued study so that we may thoroughly establish this important principle in all contracts with third parties, including the State Welfare Department. Percentage discounts for those patients in some income categories will be necessary, but with one fee schedule, the economic principles upon which the physician works will be much clearer.

Congratulations go to Dr. Peers Buckley, the president-elect, who comes to office with an unusually broad background of state medical activity. He will welcome, I am sure, any suggestions concerning the content and the length of the 1966 meeting in Duluth. Again, thanks to all who made the 1965 meeting an outstanding event. We anticipate similar support next year.

WITH HAND WEIGHT OFF
ADD 20 GRAMS TO READING

Keeping an eye on the scales may be an avocation with some people, but it is a full-time occupation for Lilly employees who determine the weight of filled tubes of medication. First, a random sampling of empty tubes is taken, and the average weight is calculated. Then, the amount of ingredient is added to this figure to determine the standard fill. As the machine fills the tubes, a sample—about one out of every four hundred—is weighed and checked against the standard. The weights are plotted on a graph. A variation of three consecutive points in either direction indicates a trend away from the standard, and the machine is adjusted. Tolerances are kept to less than 5 percent. An extra step . . . but consistent with the meticulous program at Eli Lilly and Company to assure the highest quality in our finished products.

Collapsing Hip Nail

A Review of 132 Patients

Treatment of hip fractures has improved with use of a collapsing hip nail. One hundred thirty-two patients are reviewed in this article and results indicate superior function and rehabilitation with this device.

GILBERT F. MUELLER, M.D.*
JOSEPH C. KISER, M.D.*
THEODORE A. PETERSON, M.D.*
MALVIN J. NYDAHL, M.D.*
CLAUDE R. HITCHCOCK, M.D., Ph.D.*
Minneapolis, Minnesota

THE SLIDING NAIL is a valuable and workable adjunct in the treatment of hip fractures, especially those of the femoral neck. The experience at the Minneapolis General Hospital using the Massie Sliding Nail indicates that the rate of aseptic necrosis and/or nonunion following femoral neck fractures is less than can be expected using other methods of fixation.

The most common fractures requiring operative treatment are those involving the hip. Historically, prior to Whitman's classic presentation in 1920 of nearly 90 per cent healing in femoral neck fractures treated by adequate reduction and prolonged casting, this injury bore the stigma of a major tragedy, most certainly portending a prolonged disability and often death to the unfortunate elderly patient.[1] In 1931 Smith-Peterson introduced the well known triflanged nail as a method of internal fixation. This method of treatment significantly altered the concepts of therapy and remains today as a common method of fixation. Results using the Smith-Peterson nail vary from 60-85 per cent satisfactory union.

The Telescoping Nail

Dr. William K. Massie of Lexington, Kentucky, has recently devised a telescoping nail designed to avoid some of the common complications involved in operative methods of treatment for fractures of the hip.

Advantages

The theoretical advantages of this nail are: (1) Angle of the nail — 150°; (2) Telescoping device permitting impaction of the fracture; (3) Maximum purchase in the femoral head; (4) Early ambulation; (5) Single nail size.[2,3]

---

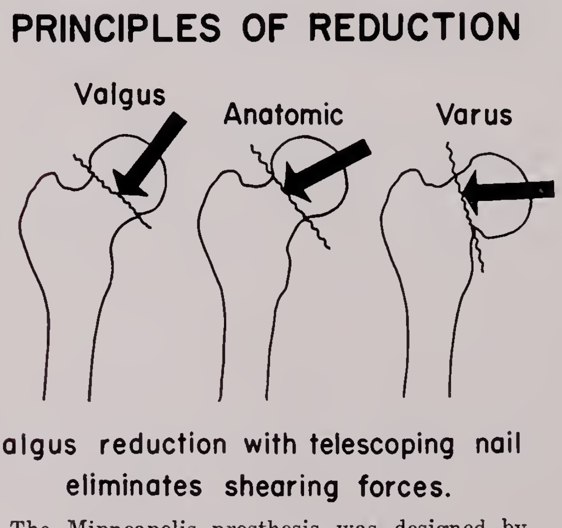
*Department of Surgery, Hennepin County General Hospital, Minneapolis (Formerly Minneapolis General Hospital).

Accurate reduction is of great importance for the proper utilization of the Massie nail. The head must be in anatomic or slight valgus position with the medial trabeculae of the femoral neck and head at an angle between 160 and 180° with the medial femoral cortex in the anteroposterior plane. The trabeculae should be at 180° in the lateral projection. This fracture is then subjected essentially to a compression force,[4] thus eliminating to some degree the shearing forces which tend to retard healing.

Following insertion of the nail and release of traction the nail collapses to some degree in the majority of cases, a feature which eliminates penetration into the acetabulum as impaction at the fracture site continues.

Results

Dr. Massie reported 90-per cent healing using this nail in the treatment of femoral neck fractures. The greatest test of any new form of treatment is its efficiency in the hands of others. We, therefore, have analyzed our series of Massie nail fixations done at Minneapolis General Hospital by residents and occasionally by interns under resident supervision. We began using the Massie nail in 1959 and since then have used it in over 160 patients. Our presentation here centers on 132 patients, with follow-up of one to three and one-half years. Of these, 84 were intertrochanteric fractures and 48 femoral neck fractures, in patients ranging in age from 44 to 101, with a median age of 70.



PRINCIPLES OF REDUCTION
Valgus
Anatomic
Varus
Valgus reduction with telescoping nail eliminates shearing forces.

Femoral Neck Fractures

Forty-eight of the 132 patients had femoral neck fractures, all of which were displaced high neck or intracapsular fractures. None of these cases could be considered undisplaced or abducted impacted fractures. All cases required reduction. In this group of 48 patients there was one postoperative mortality. Two additional patients died of unrelated causes before healing had taken place. Three developed avascular necrosis with bony union one to two years following injury. One patient had a failure of fixation, in which the nail retracted from the head twice and required insertion of a Minneapolis prosthesis.* One had a nonunion at 10 months which was felt to be caused by a poorly placed nail, and another was lost to follow-up. Excluding the patient lost to follow-up and the two patients who died of unrelated causes, thirty-nine (87 per cent) are considered to have excellent results at this time.

We recognize that the avascular necrosis rate in this series is incomplete, since only 75 per cent of our patients have been followed two or more years and none for longer than three and one-half years. A more critical analysis of this problem must await a longer follow-up period; but results to date have been very encouraging.

Intertrochanteric Fractures

Eighty-four of the 132 patients suffered intertrochanteric fractures, all of which were displaced and required reduction. Four were fractures of the extreme base of the neck. There were no subtrochanteric or pertrochanteric fractures included in this group. Nine of these 84 patients had severely comminuted fractures. There were four postoperative deaths. Three patients died of unrelated causes prior to complete healing. In one patient the nail broke immediately below the flange sometime between four and six months post fixation.

The Minneapolis prosthesis was designed by a group of orthopedic surgeons of the Twin City Orthopedic Society. It is formed of one piece of metal and has an 8-in. tapered, flanged stem designed to engage the anterior curve of the femoral shaft for stabilization.

Pain increased, and by one year post fracture a nonunion was present, and a Minneapolis prosthesis was implanted. One patient with an extremely comminuted fracture fully collapsed the nail by the second postoperative day, and it penetrated through the acetabulum one inch. This fracture healed and the patient enjoys painless weight bearing. One patient developed wound infection which healed uneventfully. Excluding three patients who died from unrelated causes, 73 (91 per cent) are considered to have excellent results.

Comment

Our general over-all management of these patients has evolved slowly over a period of years in conjunction with the management of fixation with other types of nails. In general our contraindications to immediate surgery are conditions which can be expected to be remedied with 24-48 hours of medical management. These include: (1) Severe sepsis; (2) Cardiac dysrhythmia; (3) Extreme dehydration. With these few exceptions we feel that operation is indicated at the earliest possible time. Many of these patients undergo manipulation and fixation as an emergency procedure at night or on weekends.

Our postoperative management is directed toward prevention of medical complications inherent in this age group. This includes: (1) Early ambulation, (ordinarily the patient is sitting on the edge of the bed or in the wheelchair 24 hours after surgery). Instruction in gait training and parallel bar-walking progressing to crutch-walking is instituted 48 hours after surgery in patients where crutch-walking is felt feasible; (2) Nonweight bearing is advised for at least six weeks in the uncomplicated intertrochanteric fractures, or until there is X-ray evidence of healing in the femoral neck fractures. We find, however, that many of our patients start weight bearing immediately, and many walk without crutches after four weeks. Our patients are followed at monthly intervals until the fracture is healed clinically and by X ray.

Measurements made during healing have pointed out the advantage of the telescoping principle. The greatest measure of collapse in these fractures has been 2½ cm. In eight of our patients with fractured femoral neck and in 15 with intertrochanteric fracture, impaction at the fracture site was sufficient, so that, had rigid fixation been used, the nail would have penetrated the acetabulum.

Summary

We have reviewed 132 patients with fractured hip treated with the Massie collapsing nail. Of 48 with femoral neck fracture 87 per cent obtained good results; of 84 with intertrochanteric fracture 93 per cent obtained good results.

Gastric

Volvulus of the stomach appears to be a rare condition. It may, however, occur more frequently than is generally supposed and every physician should be aware of this condition and should consider it in a differential diagnosis of acute upper abdominal disease.

The condition has been known since Berti,[1] in 1866, reported a case discovered at autopsy, in which a stomach had twisted two complete turns. In 1895 Berg[2] reported surgical treatment of a case. Since then a considerable number of cases have been reported, and in 1954 Gottlieb, Lefferts and Beranbaum[3] found 192 cases in the literature and added 20 of their own.

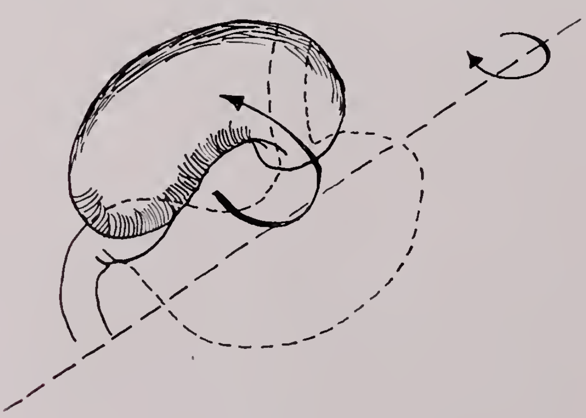

Figure 1

In 1956 Sawyer, Hammer and Fenton[4] added seven cases and pointed out that many of the previously reported cases were not true volvulus and should have been called potential, or incomplete volvulus, since the twist did not produce complete obstruction. In 1963 Guernsey and Connolly[5] added two cases in their excellent collective review and stated that about 200 cases of gastric volvulus had been reported in the literature, although many of these are probably not complete.

The condition appears to occur with equal frequency in males and females and may appear at any age, although it is most commonly seen in the age period between 40 and 60. It should be especially looked for in patients who develop severe upper abdominal symptoms after having had a traumatic rupture of the diaphragm.

The etiology of the condition is related to the anatomy of the region. It appears obvious that volvulus cannot occur unless the mesenteric attachments of the stomach are relaxed and elongated, especially in the region of the pylorus. This is usually congenital

Volvulus

R. F. NUESSLE, M.D.*
Bismarck, North Dakota

in origin and is often associated with ptosis of the stomach. Other factors which have been considered to contribute to the etiology include over-distention of the stomach, herniation or eventration of the diaphragm, gastric or extra-gastric tumors, ulceration of the stomach or duodenum. Traction by an over-distended colon or by a mobile spleen have also been considered to be possible factors in some cases.

Two main types have been described: the organo-axial and the mesenterial-axial. It is probable that not infrequently a volvulus of the stomach may represent both types.

In organo-axial volvulus a twist or rotation occurs about the longitudinal axis of the organ, that is, around a line roughly extending from pylorus to cardia. The greater curvature rotates, usually anteriorly, until it comes to lie above and in front of the lesser curvature and against, or above, the liver. The colon may come to lie stretched tightly across the posterior surface of the stomach (now facing anterior) and interposed between the diaphragm and the liver. When the twist exceeds 180 degrees, both pylorus and cardia may be expected to be obstructed (Fig. 1).

In mesenterial-axial volvulus, the twist occurs about a more or less vertical axis at right angles to the cardiac-pyloric line. The volvulus may be clockwise or counter-clockwise.

The initial effect of the volvulus is to close the pylorus by a kink or twist. The stomach is then unable to empty and begins to distend (Fig. 2). As the degree of rotation increases, the pylorus moves toward the fixed cardiac end of the stomach, folding the mid-portion of the stomach and causing a constriction (Fig. 3). As the twist and distention increase, the fold becomes a constrict-

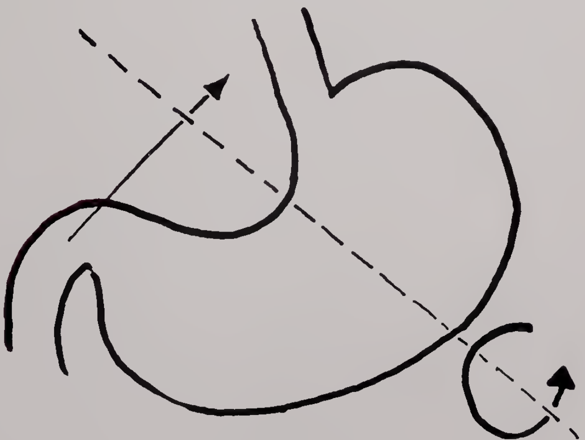

Figure 2

ing ring dividing the distended stomach into two sections. When the torsion has increased to the point where the two orifices are approximated, they form a pivot about which the further twisting of the organ occurs, obstructing the cardia (Fig. 4). At and beyond this point, the vascular supply of the stomach is endangered and may become occluded, producing strangulation. Patients in whom this occurs are extremely ill and are in peril of their lives unless the condition is quickly diagnosed and promptly treated surgically.

The symptoms are those of a high intestinal obstruction. The onset is often dramatic and sudden with severe expanding epigastric pain, often radiating through to the back, associated with a rapid onset of shock, distention and upper abdominal tenderness. At first the vomiting may be profuse, but it is shortly followed by retching and attempts to vomit without result. Ingesta are quickly rejected and attempts to pass a stomach tube are unsuccessful. These symptoms may be described as a triad: (1) attempts to vomit without result; (2) circumscribed upper abdominal pain, associated with upper abdominal and left hypochondrial* distention; (3) inability to pass a gastric tube.

In a true or complete volvulus of the stomach, x-ray examination will show distended loops of bowel in the upper abdomen and left hypochondrium, characteristically with two fluid levels. There is a malposition of the greater curvature and absence of the splenic shadow. If a barium swallow is given, the barium may not enter the stomach, and a characteristic, pointed shadow is often seen in the area of the cardia. If the cardia is demonstrable there will be found to be a low esophagogastric junction. In one of our cases the barium entered the upper portion of the fundus but could not fill the body of the stomach because of a constriction in the mid-portion of the stomach formed by the twist.

The treatment is surgical. At operation the volvulus is reduced. In some instances it may be necessary to perform a gastrotomy to relieve the gastric distention before derotation of the volvulus is possible. When derotation has been accomplished, a nasogastric tube can be manipulated into the stomach which can then be emptied. Various procedures for prevention of recurrence of volvulus have been attempted, including

---

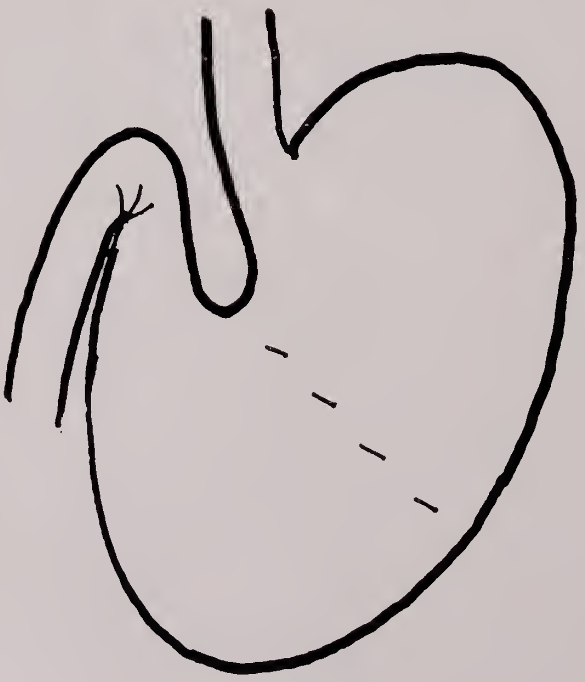

Figure 3

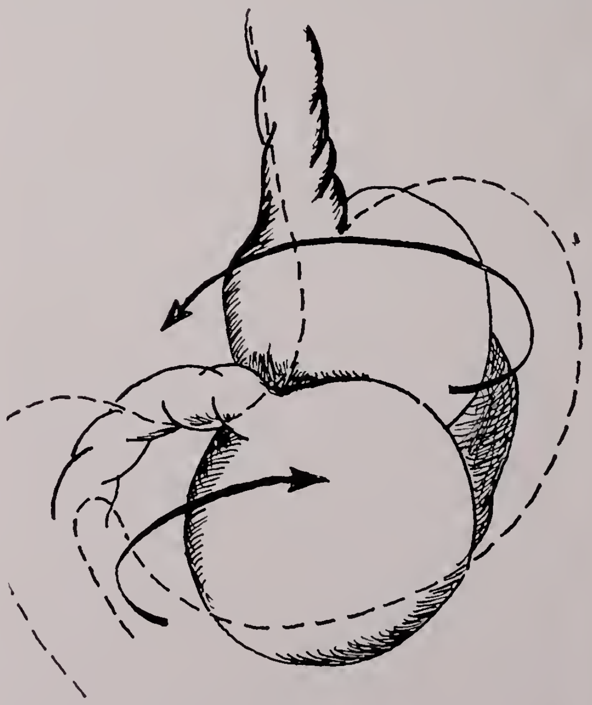

Figure 4

gastropexy, gastrectomy and gastroenterostomy. It is essential that the stomach be kept decompressed for several days after surgery and that investigations be made to rule out the possibility of duodenal ulcer or gastric carcinoma before the patient is discharged.

Case Histories

The following two cases illustrate two forms of the disease.

Case # 1

An 80-year-old white female was referred by her local doctor because of severe abdominal pain and distention for one day. The patient stated that she had been entirely well until 7 o'clock the evening before when she stooped over and suddenly noted severe abdominal pain. The pain had increased progressively, together with increasing distention of the abdomen. There had been nausea without vomiting and she had been obstipated. Previous similar symptoms were denied.

Examination revealed a rather feeble, moderately obese woman who appeared to be acutely ill. General examination did not reveal any abnormal findings except in the abdomen, which was markedly distended, mostly in the left lower quadrant. There were no masses or tenderness, and peristalsis was absent. Rectal and pelvic examination revealed no abnormality. The leukocyte count and hemoglobin were normal.

Roentgenograms of the abdomen showed a markedly distended viscus occupying the left abdomen and containing a fluid-air level. Above, and to the left of this viscus, was another gas and fluid-filled cavity with a fluid level. On the decubitus views the two cavities were separated by a short band of soft tissue. Gas-filled large bowel loops were evident on the right between the liver and the diaphragm, but only a small amount of gas was seen in the sigmoid colon. A diagnosis of volvúlus of the stomach was made by the roentgenologist.

At operation through an upper left paramedian incision, the large and small bowel were seen to be collapsed, but the stomach was cyanotic and edematous and showed tremendous distention, almost filling the abdomen. There was some serosanguineous fluid in the upper abdomen. The spleen lay anterior to the stomach, beneath the xiphoid and anterior to the liver at the mid-line, the stomach having been rotated in a counter clockwise direction. The pylorus and antrum had rotated to the left behind the cardia and were found high beneath the left diaphragm, from which they were reduced with some difficulty. Then, however, it was possible to derotate the stomach quickly and return the spleen and greater curvature to their normal location. The cardia, esophagus and duodenum appeared normal although redundant. The greatly distended stomach contained both fluid and air. The previously placed Levine tube had been advanced only to the lower esophagus, and, with the anesthetist working above and the surgeon below, it was finally possible to pass the tube into the stomach, after which 1,600 cc. of fluid and a like amount of air were evacuated from the stomach. The stomach and bowel being replaced in the normal position, the abdomen was closed in the usual manner without any other procedures.

The patient was maintained on nasogastric suction for four days, after which her recovery was uneventful.

A year later she stated she was entirely well and denied any gastrointestinal symptoms. Her general examination was normal. A roentgenogram of the stomach at this time showed chronic duodenal deformity, presumably due to scarring, since no ulcer crater could be demonstrated.

Case # 2

A 70-year-old female was seen because of persistent nausea and vomiting. She stated that four days before, after having been on a picnic, she developed nausea and vomiting which had persisted for two or three days. The day before admission she had developed abdominal distention and dyspnea but had no pain.

She had suffered three previous attacks of abdominal discomfort and distention associated with nausea and vomiting and lasting for several hours. She also had a history of fatty-food intolerance. She was known to have had a large hiatus hernia for at least 12 years.

At the time of admission she was acutely ill with abdominal distention and nausea although without pain. She was a poorly nourished and feeble old lady. The general examination showed asthmatic rales in both lung fields. The abdomen was acutely distended and moderately tender. There were no abdominal masses; rectal and pelvic examinations were normal. The blood urea was 104 mg%.

On intravenous fluids and supportive therapy she improved markedly, and on the fourth hospital day, an upper gastrointestinal study showed that the barium entered the fundus easily but did not pass beyond until an hour later, when a small amount of barium was seen in the body of the stomach. The upper portion of the stomach was twisted upon itself so that the antrum was found in the chest at the proximal fundus and the duodenum and cardia remained in the abdomen.

Surgery was carried out through a left thoracotomy. The large herniated stomach was reduced and derotated, relieving the obstruction, and the hiatus hernia was repaired. The patient made an uneventful postoperative recovery.

Summary

Volvulus of the stomach is an acute surgical emergency which occurs with sufficient frequency so that it should be kept in mind by all physicians who treat abdominal disease.

The diagnostic triad is circumscribed upper abdominal pain with distention of the epigastrium and left hypochondrium; unsuccessful attempts to vomit; and inability to pass a gastric tube.

In doubtful cases X rays are often useful in making the diagnosis. Prompt diagnosis and surgical treatment are indicated.

WHAT'S YOUR DIAGNOSIS?

A two-and-a-half-year-old boy had had a mild cold for several days that had become slightly worse the day before he was first seen. The temperature had suddenly risen to 104 degrees. His cough increased; he was grunting; there was a marked tachycardia. The breath sounds posteriorly were slightly suppressed. The abdomen appeared large; but the mother claimed that it had always been rather large.

He was given penicillin and admitted to the hospital later that day. The white count was 4,000 with slight neutrophilia. X-ray of the chest showed the diaphragm very high, and the base of the lungs appeared to be compressed. A flat plate of the abdomen revealed some distended loops of small intestine and, except for a small area, there seemed to be no air in the colon.

On the following morning the abdomen was more distended. The child held himself stiff and there was a questionable nuchal rigidity. Elevation of the alae nasi was very marked.

A consulting surgeon suggested waiting and in the meantime using gastric and duodenal suction, intravenous fluids, penicillin and aureomycin. On the following day a flat film of the abdomen showed an increase in the intestinal distention. The temperature was 104.6. The abdomen became extremely tense. The repeated white count was 5,400 with 81 per cent polymorphonuclears. Urine showed 1 plus albumin, 25 to 30 casts per high-powered field.

Three days after admission to the hospital the respiratory distress became acute and the intestinal loops were markedly distended with air. He was then taken to the operating room and a laparotomy was done.

Sclerosing Neuroma as A Cause of Meralgia Paresthetica

Another example of "Nerve Entrapment Syndrome."

THE SYNDROME, meralgia paresthetica, has been known for more than 80 years.[1,2] The term is derived from the Greek words "algos" meaning pain and "meros" meaning thigh. The syndrome is characterized by pain, numbness, tingling, burning, coldness, or itching limited to the distribution of the lateral femoral cutaneous nerve of the thigh. This area includes the anterolateral portion of the thigh extending from just below the inguinal ligament to the upper border of the patella. Symptoms also may be felt as smaller, more circumscribed areas within the larger area. Symptoms usually begin after the age of 20 years and then may disappear spontaneously or may progress in severity until the patient becomes incapacitated.

Numerous causes for this syndrome have been proposed.[3] It is now generally thought to be caused by pressure on the nerve at any point in its course before the bifurcation. Because of the nerve's superficial position and the potentially constricting fascial layers through which it must pass near the anterior superior iliac spine, this area is most likely to be associated with the underlying pathology.

Anatomically the lateral femoral cutaneous nerve is an entirely sensory nerve, generally arising from the posterior roots of L-1, L-2, and L-3.[4] Passing behind or through the iliopsoas muscle, it courses inferolaterally on the deep surface of the iliacus muscle in the iliac fascia and enters the thigh just medial to the anterior superior iliac spine and below the lateral end of the inguinal ligament. It emerges from the fascia lata at a variable point up to 10 cm. below the anterior superior iliac spine. Just before or just after entering the subcutaneous tissues, the nerve usually divides into anterior and posterior branches. Considerable variation in this anatomic pattern has been described.[5]

*Fellow in orthopedic surgery in the Mayo Graduate School of Medicine (University of Minnesota), Rochester.

**Section of Orthopedic Surgery, Mayo Clinic and Mayo Foundation.

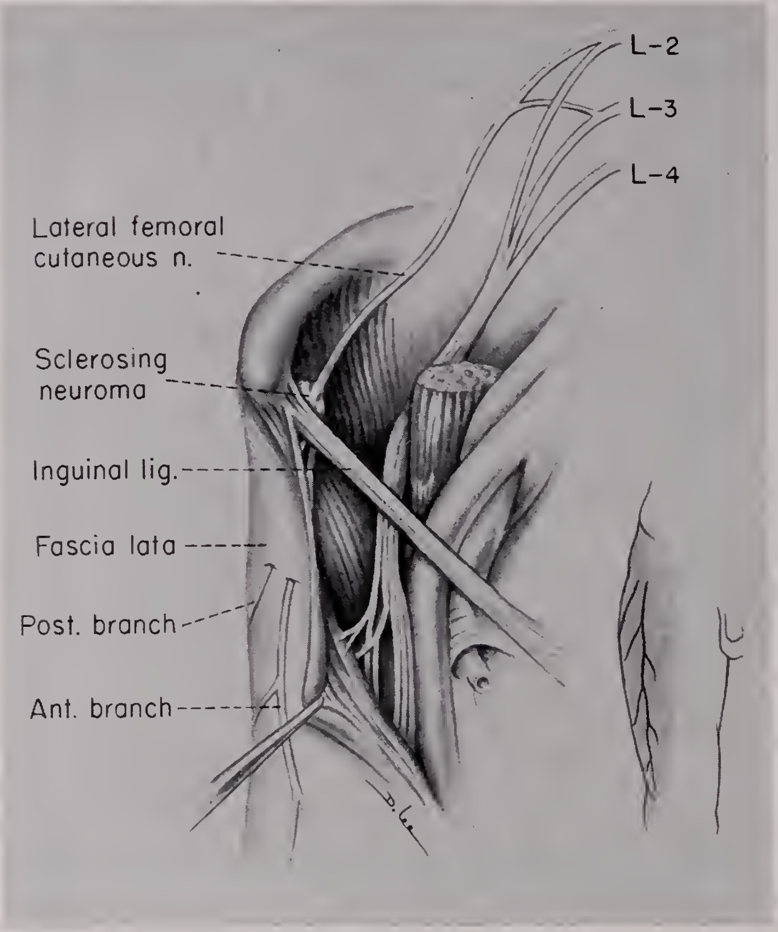

Fig. 1 — Drawing of operative site.

This paper reports a case of meralgia paresthetica caused by, or associated with, a sclerosing neuroma of the lateral femoral cutaneous nerve of the thigh.

Report of Case

The patient was a 56-year-old hospital employee who came to the Mayo Clinic complaining of pain in both hips and thighs. Approximately 20 years before he first had noticed occasional "numb, tingling, and pins-and-needles" sensations in the anterolateral part of his right thigh. More recently he had experienced occasional sharp stabs of pain and severe aching in the same region. These sensations were precipitated when he wore a belt, walked or stood for long periods, lifted heavy objects, sat in a bent or cramped position for prolonged periods, or when he pressed his finger just inside the anterior superior iliac spine. These sensations were temporarily relieved by local heat, massage, and ultrasound as well as by hot baths, meperidine, and bed rest. Ten days before he came to this clinic, the tingling and aching became constant for no apparent reason, and so severe that it interfered with sleep. For several years he had also noticed similar but not so severe sensations in the left thigh.

In addition, the patient complained of aching over both greater trochanters. This had been present intermittently for many years and, on one occasion, had been relieved for nine months by local hydrocortisone injection.

Physical examination showed only tenderness over both greater trochanters and hypoesthesia in the distribution of both lateral femoral cutaneous nerves. Roentgenograms of the lumbar part of the spinal column, pelvis, and hips were interpreted as normal.

Since the right thigh had been consistently more uncomfortable, he wished to have only that side operated on. Under local anesthesia an incision was made from the anterior iliac spine inferomedially for a distance of 5 cm. over the inguinal ligament. After the skin and subcutaneous tissues were reflected, the lateral femoral cutaneous nerve was seen (Fig. 1). The nerve was resected to include the mass (Fig. 2). The pathologic diagnosis was sclerosing neuroma; histologically the mass showed perineural fibrosis, intraneural fibrosis, and intraneural edema.

One week after operation the patient was free of symptoms in the right thigh.

Discussion

Nawratzki[6] observed a spindle-shaped swelling of the nerve adjacent to the anterior iliac spine and reported that microscopic changes in this swelling consisted of "perineuritis and interstitial neuritis." Others[7,8] have noted gross local nerve enlargement in this area but have not recorded histologic observations. We believe that meralgia paresthetica is another example of the "nerve entrapment" syndromes and that the tumor found at operation in our case represents the result of long-standing trauma or entrapment of a lateral femoral cutaneous nerve.

Summary

A patient with histologically proved sclerosing neuroma of the right femoral cutaneous nerve at the level of the anterior superior iliac spine associated with the symptoms of meralgia* paresthetica obtained complete relief of those symptoms after removal of the neuroma.

ANSWER TO WHAT'S YOUR DIAGNOSIS

(from page 996)

A small amount of straw-colored fluid was found in the peritoneal cavity. The extremely distended small bowel loops were decompressed by suction with the needle. After the entire small bowel was delivered from the abdominal cavity, the cause of the obstruction was found to originate from a large cyst which filled the entire lower abdomen and the pelvis. This cyst could not be delivered until half of its contents had been aspirated. It contained grayish foul-smelling material and was found to arise from the transverse mesocolon. After dissection from its origin in the mesocolon, it was removed. Pathologic diagnosis: Infected lymphangioma.

After a stormy convalescence, the boy recovered.

Robert Rosenthal, M.D.
St. Paul, Minnesota

BRENNEMANN'S SYNDROME

(Abdominal Syndrome)

This is the abdominal manifestations of pain and cramps occasionally associated with acute or subacute rheumatic process in the child. This needs differentiation from acute mesenteric lymphadenitis.

The presence of C-reactive protein, an elevated sedimentation rate and antistreptolysin O titre strongly suggest rheumatic fever and should, therefore, aid in the diagnosis.

Durham — Encyclopedia of Medical Syndromes.

Drive Safely

There are two kinds of finishes you can put on an automobile — lacquer and liquor.

Lymphangiography

Study of lymphatics in clinical patients is a rapidly growing adjunct to diagnosis of hidden malignancies.

FOLLOWING THE work of Kinmonth,[5,6] interest was restimulated in attempts to visualize the lymphatic system. Further studies by Wallace[8] posed the question: how would lymphangiography help radiologic diagnosis and therapy in our department. The answer could only be obtained, if at all, by a series of cases with no restriction on presenting diagnosis. The arbitrary figure of 100 studies was selected; seventy-nine of them were of value and twenty-one were discarded due to technical problems. The method advocated by Wallace[8] has been followed, with modifications introduced to suit the local situation and apparatus involved.

Excellent analyses and descriptions of the lymphatic system have been produced in the recent literature.[2,4,7,8]

Technic

Initially a weak solution of Patent Blue V was injected intradermally into the dorsal webs of the toes or fingers. Later, a saturated solution was used with greater success. The amount injected is not important; if a small wheal is raised, as with a Mantoux test injection, satisfactory absorption is obtained. The skin lymphatics in young individuals will appear almost immediately; but with older patients multiple injections may be required.

The skin lymphatics usually lie over deeper channels. Using these channels as a guide, a longitudinal skin incision is made alongside a channel on the dorsum of the member and is elongated as required. The small blue lymphatic channel is elevated and cleared of all tissue. Usually the vessel goes into spasm, and milking of the channels distally will engorge the vessel. While visualizing the area with magnification the vessel is elevated and nicked with a pair of sharp scissors. A blunted 27 or even 25-gauge hypodermic needle with swedged-on polyethylene tubing is inserted into the channel. The blunting of the needle prevents perforation of the vessel. Five cc. of Ethiodal (38% iodinated poppyseed oil) in a 10-cc. syringe is attached to the tubing. A common retort stand with a clamp to hold the syringe and another ring clamp over the plunger to hold the graduated weights provide satisfactory, continuous flow. Usually the 5 cc. can be injected in one hour. Some extravasation is always present, but this should be disregarded and the injection

MILTON R. GILCHRIST, M.D.*
St. Paul, Minnesota

A Local Evaluation

continued. Originally 15 cc. of Ethiodal was used, but this amount was gradually reduced to 5 cc. with a marked saving of time and with equally good visualization. Routinely, films have been obtained of the pelvis, abdomen, and chest at the end of the injection and at 24 hours. Extremity films have been obtained only if a block is suspected.

Material

Seventy-nine studies have been completed. These include the following: 36 lymphoma, 25 carcinoma, and 18 miscellaneous. Early studies have not been included due to technical difficulties — chiefly incompleteness due to inexperience. Twelve patients are now deceased; autopsies have been obtained and recorded in ten.

Results

Lymphoma

The lymph channels have a normal appearance unless there is a proximal obstruction, in which case the channels are distended. The lymph nodes absorb a part of the contrast material and have a lacy irregular pattern. The nodes show enlargement, particularly marked in lymphatic leukemia. If the node is totally involved with lymphoma, filling does

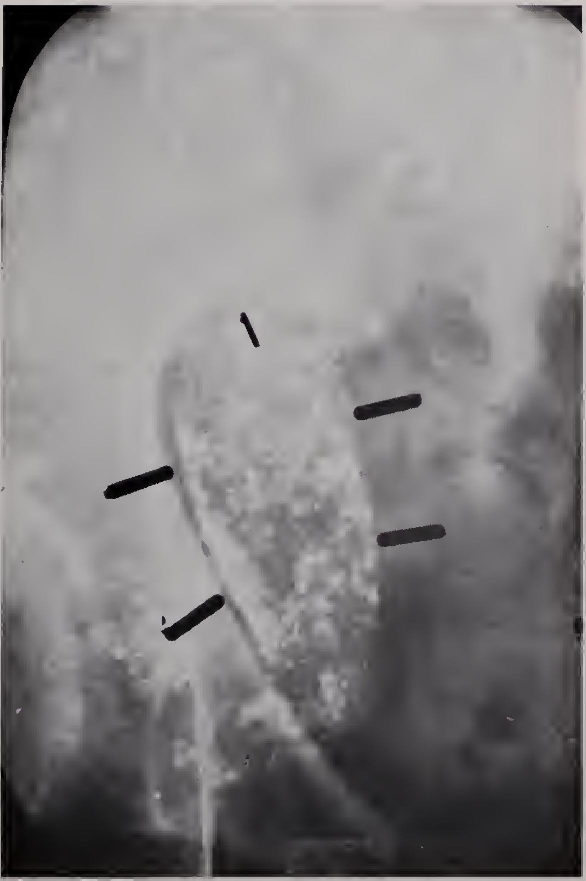

Fig. 1 — Male, aged 65, with chronic lymphatic leukemia. Note the lacy, irregular filling pattern of the enlarged node.

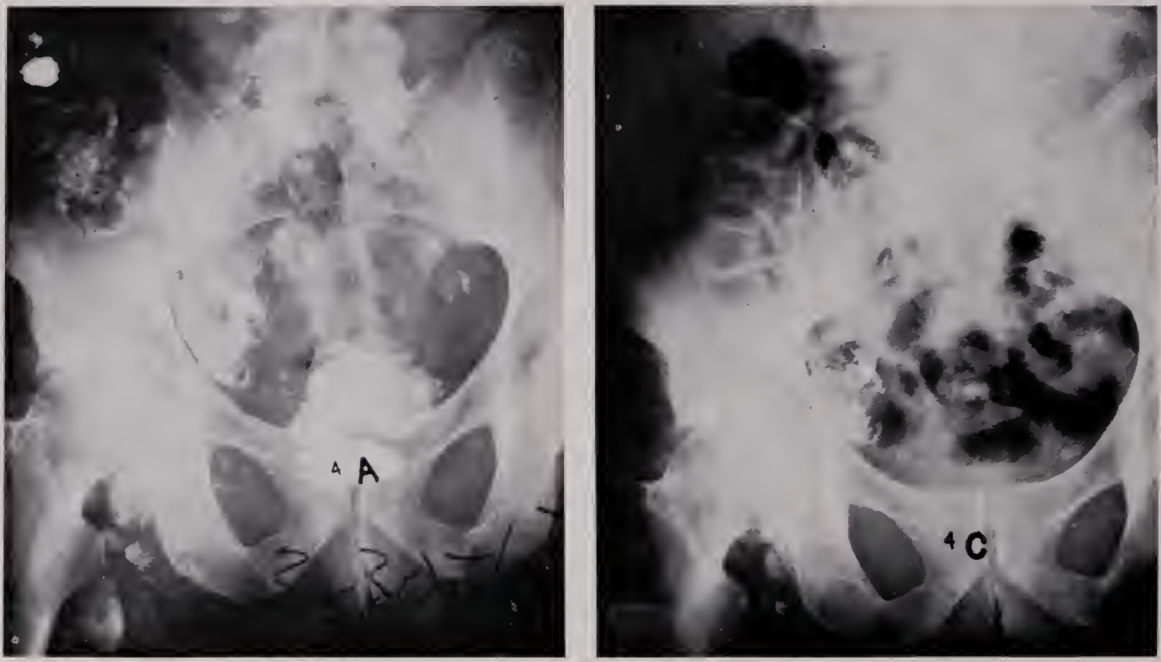

Fig. 2 *(left)* — Male, aged 50, with lymphosarcoma. In 3-30-63 the right femoral, inguinal, and iliac nodes have the typical enlarged feathery pattern. *(right)* Follow-up film 7-1-63 after radiation therapy — second injection demonstrates a marked decrease in the size of the nodes with least effect in the parailiac area.

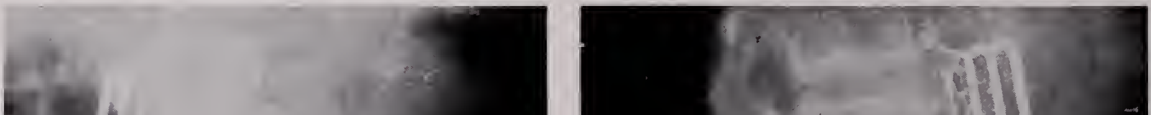

Fig. 3 — Male, aged 58, with carcinoma of colon. *(left)* The lymphatic channels are engorged and dilated to the level of the pelvic brim. *(right)* Proximally there is a block and the channels are fewer and deviated around several very large unopacified nodes. (A colostomy had previously been performed.)

not take place and a gap is left in the chain. The lymph channels may be deviated, indicating the presence of involved nodes (Figure 3).

Carcinoma

The metastases to the nodes are not visualized, but the nodal tissue takes up the contrast, giving a motheaten appearance. The afferent lymphatic channels may enlarge. Occasionally an increased number of channels and nodes may be visualized.

Lymphatic Obstruction

There must be great damage to the channels before lymphedema occurs. When a block to lymph flow is present, collateral lymph channels open and multiply, and bizarre patterns of drainage are demonstrated (Figure 4). Often the edema of the part is due to an obstructed vein; consequently venography should accompany or preferably precede a lymph-channel study.

Inflammation, retroperitoneal fibrosis, and

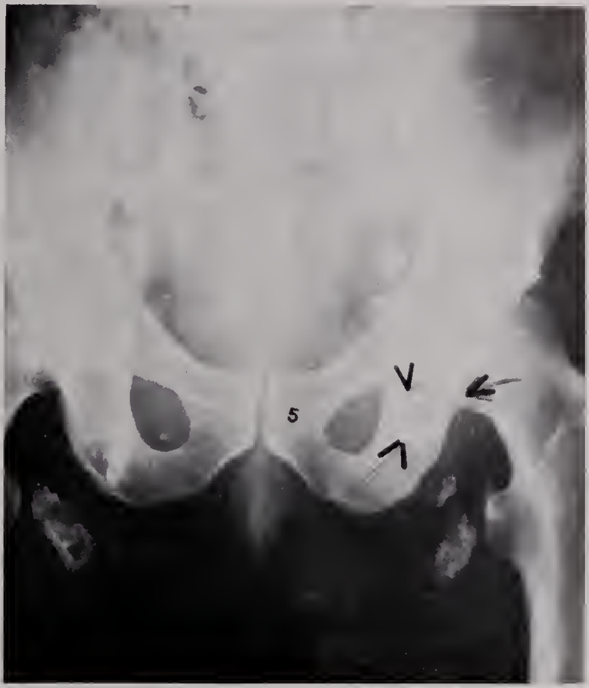

Fig. 4 — Male, aged 38, with carcinoma of urinary bladder. Nodes in left femoral area removed and sectioned. These contained carcinoma in the vaculated central area and normal lymph tissue at the periphery.

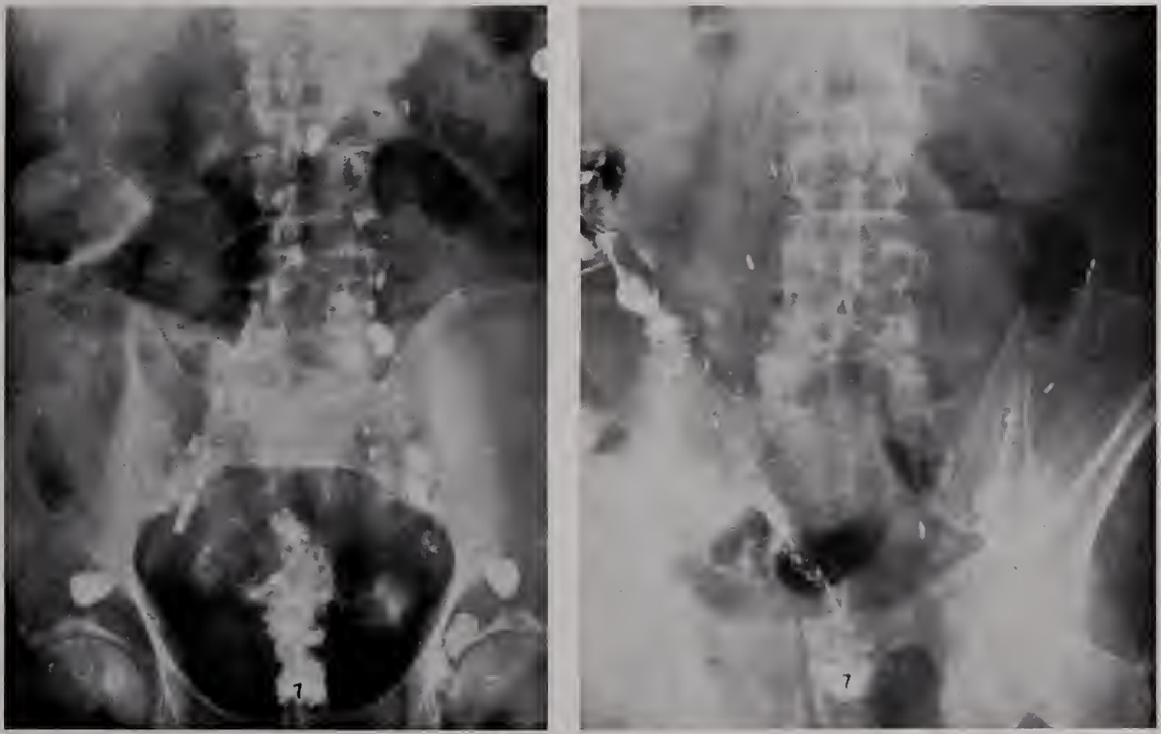

Fig. 5 — Male, aged 70, with carcinoma of rectosigmoid colon. *(left)* Preoperative film of lymphatic system — note involved nodes in parailiac and inguinal areas. By agreement the surgeons applied metallic clips in areas where nodes were removed. *(right)* Postoperative film obtained several months later (due to complications) discloses that the clips do not necessarily parallel the specified areas.

carcinoma situated elsewhere than in the pelvis show indeterminate results, in which the lymph nodes enlarge but show no characteristic pattern. The lymph channels may be decreased or increased but again without any determining pattern.

Use

Lymphangiography has proven to be of assistance in both radiologic diagnosis and therapy.

Diagnosis: (categories)

1. Suspicion — where there is an unproven but suspected diagnosis of lymphoma or carcinoma.
2. Location — to ascertain if disease is present in a certain location either initially or after treatment.
3. Extent — to determine location or diffuse involvement.

Therapy —

1. Radiation — as an aid in better localization, field size, sparing of normal structures, and determination of effectiveness.
2. Surgery — for better visualization and typing of nodes before, during, and after surgery.
3. Chemotherapy — for evaluation and follow-up.

Complication

A great deal has been written about oil embolism and lung involvement.[1,3,8] In all our cases no oil embolism and no lung abnormality were noted by impartial observers. No allergic manifestations of any kind were encountered. One wound infection occurred in a severely debilitated individual. Our good fortune may be due in part to the small series and/or to the small amount of contrast injected.

Isotopes

Iodine^{131}-tagged Ethiodal was injected and scanning procedures were attempted, but no definitive pattern could be obtained.

Radiation therapy with isotopes was not attempted, as it was concluded from pathological studies that the normal part of the node absorbed the contrast material and consequently would receive the most radiation, while the malignant portion absorbed little or none at all.

Conclusions

Lymphangiography is a relatively innocuous but tedious procedure.

Lymphomas yield the best positive results with carcinoma in the pelvic area running a poor second.

Lymphangiography provides a means of evaluating regional lymph-node status.

In radiation therapy, lymphangiography provides an aid as to type, duration and placement of therapy and is of special value in the follow-up of the patient.

Localization of nodes before, during, and after surgery has been developed.

When edema of an extremity occurs, a venogram should precede a lymphogram to determine the cause of blockage.

Isotopes have not been of benefit in either radiation diagnosis or therapy — in conjunction with lymphangiography.

Seventy-nine studies of the lymphatic system have been concluded for assessing the value of lymphangiography in a local large metropolitan hospital. It has been determined that lymphangiography is an aid in both radiation diagnosis and therapy in carefully selected cases.

Wheezing Infant[*]

- *Management*
- *of*

STUART LANE AREY, M.D.
Minneapolis, Minnesota

ASTHMA IN infants presents some marked differences from the picture in adults. Some infants have the typical multiple musical expiratory rales, while others have a chronic cough with coarse, moist rales throughout the chest. During an acute attack of asthma these infants appear to be comfortable when lying down, whereas children will assume a sitting posture. The management of these infants is always a challenge. They may wheeze from inhalants, from foods, from infections, or from a combination of any of these factors; nevertheless most of them can be helped without elaborate workup.

Allergic Wheezing

Case Report

A child was born 11-10-60, the fourth to a mother with seasonal pollenosis. His formula was evaporated milk; fruit was fed him at two months and cereal at three months. At age four months he had some episodes of wheezing, coughing and questionable cyanosis. He did not appear acutely ill although he had sibilant rales throughout his chest. He was still wheezing a month later despite treatment with three per cent aqueous ephedrine, three drops every four to six hours. The mother was instructed to do individual feeding tests for wheat, oat, corn and milk — by omitting all forms of each food for four days and then feeding the omitted food on the fifth day.[1] The test with milk was positive. He was off milk and all milk products (most breadstuffs contain milk) until fourteen months of age when milk was reintroduced without causing symptoms. At the age of five he is eating everything but is rotating his diet, i.e., getting a different food of each food family each day. He represents the most benign type of wheezing infant, who makes a complete recovery without the help of a single skin test.

Skin Testing

When the asthmatic episodes are not controlled by dietary and environmental control, skin testing may be in order. Scratch tests for foods in infants are generally unrewarding, but several authors have stressed the prognostic significance of a positive scratch test to egg;[2] i.e., a poor prognosis for ultimate recovery. Intradermal tests for ragweed, alternaria, hormodendrum and house dust in an infant and subsequent hyposensitization are often indicated. When it is not feasible to do individual feeding tests, a provocative intradermal feeding test[3] is sometimes indicated for any food the child is ingesting, i.e., wheat, corn, egg, milk, soy and yeast. This test is made by injecting intradermally .05cc. of 1:5 dilution of the food in two sites on the upper arm, observing the child for ten minutes, and then injecting .02cc. of a 1:25 dilution intradermally and observing the patient ten more minutes. This test is probably 80% accurate.

Environmental allergens such as feathers are also important. In one dramatic case the cure came from getting rid of a feather puff which was a family heirloom.

Treatment

Drugs used in the management of asthma are used as in the older age group: sympathomimetics such as ephedrine and epinephrine; bronchial muscle relaxants such as aminophyllin, and expectorants such as potassium iodide.

---

[*] Presented at the Fall Refresher Course of the American Academy of General Practice, September 16, 1964, in Minneapolis.

Asthmatic (capillary) Bronchitis

Asthmatic bronchitis begins as an upper respiratory infection. In a short time the infant develops rapid grunting respirations, a high fever and typical asthmatic rales throughout the chest. An X ray of the chest will usually be interpreted as showing a bronchopneumonia. Although the infant may be extremely toxic, the prognosis for recovery is good. Treatment consists of antibiotics, liquids and bronchodilators. Invariably there will be a family history of allergy; but not all of these children go on to develop true asthma.

Aspiration Pneumonitis

Aspiration pneumonitis may come from petroleum products either ingested or in the form of oily nose drops. In the case of ingestion of petroleum products such as kerosene, the question of the advisability of gastric lavage is unresolved. Most pediatricians feel that gastric lavage is not indicated.

Cystic Fibrosis

Cystic fibrosis is certainly the "bete noir" of anyone studying allergy, since the presenting symptom may be wheezing. The picture is complicated because some 15% of all cystic fibrosis patients also have allergic asthma. The diagnosis is confirmed by finding a high level of chlorides in the sweat, which may be collected by iontophoresis or by individual sweating in a plastic bag. (The latter procedure carries with it the very real risk of heat prostration and a fatal outcome.) Assay of the duodenal juice for trypsin is also diagnostic but technically more difficult than the above procedures. Both Shwachman's palmar sweat test and the assay of stool trypsin by digesting the gelatin of an X-ray plate fail to give a valid indication of the disease.

Case Report

This child was born normally, but during the neonatal period he developed signs of a bowel obstruction which was felt to be mechanical by the surgeon consulted. The X-ray department suggested the possibility of a meconium ileus. He recovered and did well until two months of age, at which time he had a choking spell while eating vegetables. Subsequently he had almost continuous difficulty with wheezing and loose stools. There was moderate improvement with dietary manipulation. At five months of age he was hospitalized; a palmar sweat test was normal and a chest X ray was not diagnostic. He was sent home but was readmitted to another hospital a few days later because of a recurrence of wheezing. He was started on antibiotics, but his condition deteriorated. A bronchoscopy showed no foreign body but did show an allergic-looking mucous membrane. At this time an iontophoresis was done, which showed the sweat chlorides to be 68 meq/liter. After a very stormy course, he expired. An autopsy confirmed the diagnosis.

This case emphasizes two points: first, that a normal palmar sweat test does not rule out cystic fibrosis and second, that any asthmatic infant who does not respond promptly to management should have the benefit of a sweat-chloride determination before an extensive allergic program is undertaken.

Cystic Fibrosis-Like Syndrome

There is another very definite syndrome: that of the fibrosis-like child who responds to the same management as that for cystic fibrosis, but in whom such a diagnosis cannot be made by the laboratory. Dr Warren Warwick[4] tells me that he had several of these youngsters in his cystic-fibrosis clinic at the University of Minnesota.

Case Report

A boy was born 2-12-63 and did well until 10-63 when he was admitted to St. Mary's Hospital with pneumonia and an interstitial pleural effusion. He was treated with antibiotics and made a slow recovery. Examination of the serum proteins by electrophoresis was normal; total protein was 7.6 mg. per cent with albumin 3.7 and globulin 3.9; an iontophoresis showed normal sweat chlorides. He went home on 10-23 and was readmitted 11-14 with another episode of pneumonia which was treated with antibiotics. Hospitalization lasted eight days. He remained well for five days and was again admitted for pneumonia. He was then hospitalized for ten days, during which time the diagnosis of allergy was entertained. He was sent home 12-7 on an elimination diet. He continued to cough and wheeze and was readmitted 2-15-64, at which time a barium swallow was normal. He was sent home 2-26 and readmitted 2-29 with bilateral otitis media. An X ray of the chest showed only a peribronchial infiltration. He had moderately coarse inspiratory rales throughout the chest, which were not typically asthmatic. A cine X ray of the esophagus, a screening test for gamma globulin, and a repeat sweat chloride were all normal. He was treated with antibiotics. The ears cleared, and he was then kept in a tent during naps and at night was given postural drainage as for cystic fibrosis. On 3-22 he was tested intradermally for ragweed, grass, house dust, alternaria, hormodendrum, cephalosporium and two mold mixtures, with negative results. In addition, provocative food tests were done for wheat, corn and milk with negative results. He has been kept on inhalations and postural drainage as for cystic fibrosis and so far has remained out of the hospital.

This patient wheezed, had repeated bouts of pneumonia, and has responded to cystic fibrosis management but does not have the laboratory findings of the disease.

Lobar Emphysema

Lobar emphysema is characterized by emphysematous expansion of one lobe so that dyspnea and cyanosis are produced. These symptoms may progress slowly or extremely rapidly until serious respiratory difficulty develops. One lobe, usually the upper, less often the middle and rarely a lower, is involved. Spells of dyspnea and cyanosis usually are the first symptoms. Wheezing respiration is not infrequent. On physical examination there will be an area of hyper-resonance with air entry diminished over the affected lobe. X ray will show the affected lobe to be translucent with adjacent lobes compressed or atelectatic. The heart is shifted away from the lesion. Treatment is lobectomy, although Korngold and Baker[5] temporized in two cases by performing lung punctures and withdrawing 200-300 cc. of air. This was followed by pneumothorax which cleared after thorancentesis. These are the only two cases in the literature cured in this manner. Leape and Longino[6] decry the use of lung puncture and feel the only valid treatment is lobectomy.

Extrinsic Causes of Wheezing

Extrabronchial pressure due to enlarged hilar nodes from tumor or tuberculosis may cause wheezing respiration. The treatment is the care and cure of the underlying disease.

Foreign bodies may be opaque or nonopaque. In my experience the most common nonopaque foreign body is a carrot, although the first foreign body I ever saw in a private patient was the cartilage from a chicken "drum stick" in a nine-month-old infant.

Congenital Abnormalities

Vascular Anomalies

Compression of the trachea and bronchi by vascular anomalies may cause wheezing in infants. The development of the aortic arch is effected by a complicated evolution of the primitive paired aortic arches. The symptoms depend on the location of the aberrant vessels and the degree to which they comprise the esophagus and trachea. Usually respiratory signs are more prominent than esophageal ones. Respirations are generally stridulous; but in many children expiratory wheezes, rather than inspiratory stridor, are heard. All signs may be agggravated by respiratory infections which are common in these babies. Severely affected babies lie with head extended, with flexion of the neck exaggerating the distress. Plain X rays may show the trachea with narrowing above the carina and displacement in either the horizontal or sagittal plane. Usually the most helpful X-ray sign is compression of the esophagus demonstrated with a barium swallow. Treatment is surgical.

Case Report

A boy, born 3-11-57, was well until two and a half weeks of age when the mother had to wean him because of lack of breast milk. He developed wheezing, which continued until 4-11, when he became cyanotic, was hospitalized and given ACTH. (His father had eczema and his mother had angioneurotic edema.) When there was no improvement with ACTH he was sent to Minneapolis. On physical examination his chest was full of inspiratory rales. An X ray showed a deep, rounded pressure defect posteriorly in the esophagus and a lesser indentation anteriorly at the same level. At surgery a double aortic arch was found; the anterior portion was divided. When last heard from in 1962 he was having no trouble.

Anomalous Left Pulmonary Artery

A fascinating variant of the above syndrome is a respiratory obstruction due to an anomalous course of the left pulmonary artery.[7] In the typical story, a newborn develops respiratory distress characterized by prolonged expiratory phase accompanied by wheezing. The right chest is hyper-resonant and breath sounds are decreased on this side. A chest film shows multilobar emphysema with a shift of mediastinum to the left. Later this mediastinal shift may disappear and emphysema becomes generalized. A barium swallow will show an anterior esophageal indentation near the level of the carina. On bronchogram the right mainstem bronchus will be constricted near its origin and the trachea deviated to the left.

This anomaly is characterized by an elongated pulmonary trunk following the course of the right pulmonary artery. A left pulmonary artery arises extrapericardially from this trunk. The left pulmonary artery lies anterior and superior to the right main-stem bronchus and posterior to the trachea. The right main-stem bronchus bears the brunt of the compressing force and the esophagus is compressed anteriorly.

Treatment consists of dividing the artery and rerouting it to its usual anterior position in relation to the trachea.

Tracheo-esophageal Fistula

A common anomaly familiar to most physicians is the syndrome of the usual tracheoesophageal fistula with cyanosis and choking after ingestion of food. One rare form of this syndrome is the H-type fistula with no esophageal atresia and a fistulous opening between the trachea and esophagus. Criteria for diagnosis are coughing, choking and cyanosis after ingesting fluids. There is no difficulty in swallowing; the distress occurs a few seconds later. Clear lung fields become full of coarse rales and rhonchi after swallowing. There are no symptoms after gavage* feeding. There is gastric distention after crying, straining and coughing. Confirmation of the diagnosis by X ray or esophagoscopy may be most difficult and cinefluorography has been most helpful. Treatment is surgical division of the fistula.

Cardiac Anomaly

A large left-to-right shunt from congenital cardiac disease may cause wheezing respiration. The diagnosis is usually obvious and treatment depends on the underlying cardial pathology.

Parasitic Disease

Visceral larva migrans[8] is rare in infants; it is usually seen in children older than a year of age and is manifested by leukocytosis, eosinophilia, hyperglobulinemia, hepatosplenomegaly and pulmonary infiltration. Diagnosis can be made with some certainty if there is a history of pica in a child who has a cat or dog, and with greater assurance by the finding of fertile toxocara ova in the soil or in the feces of the suspected animal.

The disease is caused by the ingestion of embryonated ova or dog or cat round worms, i.e., Toxocara canis or Toxocara mystax. Rashes of various kinds may appear. Pulmonary infiltration leading to respiratory distress, usually with wheezing, may be the most prominent manifestation or may even result in death. Treatment consists of antibiotics, steroids, and cautious trial of antihelminthics.

Summary

A wheezing infant is a diagnostic challenge. If there is a strong family history of allergy, allergic management may be tried. If there is not a prompt response, tests for cystic fibrosis should be carried out.

In infants with respiratory distress, a plain X-ray film may reveal emphysema in one lobe. In other infants a barium swallow may show esophageal compression due to vascular anomalies.

Foreign bodies either opaque or nonopaque to X ray may be suspected on the basis of history and on physical and X-ray findings.

Any child with repeated episodes of pneumonia associated with difficulty in swallowing or gastric distention after cough or straining should have the benefit of cinefluorography.

If there is pulmonary infiltration, eosinophilia, or hepatosplenomegaly in a toddler with pica who has a dog or cat, visceral larva migrans should be suspected.

Character is what you are in the dark. — Dwight L. Moody

a Method of Measuring Psychiatric Diagnostic Skills

Physicians vary widely in their ability to successfully manage psychiatric problems. The authors present a method for screening medical students and young physicians for capabilities in psychiatric work.

BRUCE H. HILLER, M.D.*
FLOYD K. GARETZ, M.D.**
RICHARD W. ANDERSON, M.D.**
Minneapolis, Minnesota

THE GROWING recognition of the problems of mental health in recent years has been paralleled by a growing recognition of the need to teach psychiatric knowledge, skills and attitudes to physicians. Psychiatric instruction has been increasing at both the undergraduate and graduate levels of medical training.

The University of Minnesota Medical School has in recent years greatly expanded its teaching programs in psychiatry, currently taught in all four years of medical school. The junior medical students have a ten-week exposure to inpatient psychiatry, and the senior medical students spend six months in the outpatient Psychiatric Clinic as part of their total clinic experience. The numbers of specialists in training in psychiatry at Minnesota has also greatly increased in recent years.

With this increased teaching activity has come the need to better understand and appraise methods and results of our various teaching programs. Both local and national research in appraising psychiatric teaching has become an important segment of investigation. Garetz and Magraw[1] are currently investigating changes in attitudes in medical students as a result of six months' intensive experience in Psychiatric Clinic. Stoller and Geertsma[2,3] have produced a sound motion picture of a psychiatric interview which they found to be a useful vehicle in testing psychiatric skills. Salzman and Goldstein[4] have used taped recordings to measure psychiatric skill.

The research reported in this paper was an attempt to use the method of Stoller and Geertsma to construct a test of clinical psy-

---

*Senior Resident, Department of Psychiatry and Neurology, University of Minnesota Medical School, Minneapolis, Minn.

**Respectively Assistant Professor and Professor, Department of Psychiatry and Neurology, University of Minnesota Medical School.

The authors wish to express their sincere appreciation to the many individuals who, as consultants, advisors and subjects, made this research possible.

chiatric skills that would be of use in a local setting. They filmed a psychiatric interview, and the film was then shown to the staff psychiatrists, who described the patient using a Q-sort method.* With the staff Q-sort as a criterion they then tested various groups of subjects such as medical students in various years of training, college students, and psychiatric residents. They found that their method significantly differentiated groups at different levels of training and that the differentiation was in a direction that was predictable (i.e., skill increased with experience and training).

In order to apply this method in our setting, it was necessary to establish our own criterion, using staff people from our own department. When this was done, the film and Q-sort were used on medical students at various levels, social workers and psychiatric residents. Tables 1 and 2 summarize the data of this research.

Table 1 is a summary of data for four groups studied. Mean score represents the average score for that group and reflects the group deviance from the staff psychiatrists' criterion. The higher the score the less skilled the member of the group. Standard deviation represents the standard deviation of distribution of scores for the particular study group.

Table 2 shows the tests of significance when comparing the study groups, one with another. Table 2 indicates that there was a statistically significant difference between each group when compared with every other group — with the exception of the comparison between the psychiatric residents and social workers. The table further shows that the test result for each group is in the predicted direction in terms of the amount of experience of that group (i.e., staff psychiatrists show more skill than psychiatric residents, who show more skill than senior medical students, who show more skill than junior medical students).

TABLE 1

This is a summary of data for four groups studied. Mean score represents the average score for that group and reflects the group deviance from the staff psychiatrists' criterion. The higher the score the less skilled the member of the group. Standard deviation represents the standard deviation of distribution of scores for the particular study group.

Study Group	Mean Score	Standard Deviation
Staff Social Workers	70.13	15.00
Psychiatric Residents	70.21	12.57
Senior Medical Students	82.36	19.27
Junior Medical Students	91.91	12.02

TABLE 2

This is a summary of tests of significance. Each study group was compared with each other group to determine if differences in mean score were statistically significant.

	Social Worker	Psychiatric Resident	Senior Medical Student	Junior Medical Student
Social Worker		$t = .01$ $p > .9$	$t = 2.35$ $p < .02$	$t = 4.21$ $p < .001$
Psychiatric Resident			$t = 2.66$ $p < .02$	$t = 4.77$ $p < .001$
Senior Medical Student				$t = 2.67$ $p < .01$
Junior Medical Student				

The results of this research confirm the work of Stoller and Geertsma and point to the possible usefulness of the method in testing medical students and residents for their psychiatric diagnostic skill. This research also suggests the possibility of using this method and other similar methods to study the effectiveness of various psychiatric teaching methods.

Summary

A film of a psychiatric interview and a set of descriptive statements were used to establish a method of measuring psychiatric diagnostic skill in medical students and psychiatric residents. Skilled and experienced individuals performed better on this test than did less skilled and less experienced individuals. This method has promise as a technique of testing medical students and psychiatric residents as regards their psychiatric diagnostic skill.

---

*Q-sort method is a method of quantifying descriptions. The subject is asked to sort a series of descriptive statements into usually seven to nine categories in terms of how characteristic the statement is of the subject being described. This method allows for quantification of the description and also quantitative comparison of descriptions of various individuals or groups.

IT'S THE LAW

Blood Alcohol .15% Scientific Yardstick of Intoxication

A trial court was justified in concluding, upon all the evidence, that a driver had been proved guilty beyond a reasonable doubt of operating a car while under the influence of intoxicating liquor, a Connecticut intermediate appellate court ruled.

The driver was arrested when he was found slumped over in the front seat of a car either asleep or in a stupor. The car was in a stationary position in the middle of a parking lot obstructing traffic but its motor was running. The car had rolled out of a parking stall.

The officer aroused the driver after some difficulty and took him to the police station. The driver was unsteady on his feet, his breath smelled of alcohol, his eyes were blood-shot, and his speech was thick. He admitted that he had had several bottles of beer. The driver consented to a blood test which showed a blood-alcohol content of 0.16 per cent.

It is settled medical opinion that any person is unfit to drive when his blood-alcohol concentration is 0.15 per cent or more. The standards of the AMA, which are practical and fair, even generous, adequately served the purpose of providing a scientific yardstick of reasonable accuracy for evaluating the condition of a person accused of operating a car while under the influence of intoxicating liquor, the court said.

The car had to have been "operated" by somebody to get where it was found with the driver in it. There was sufficient circumstantial evidence to show that the driver had "operated" it while under the influence of intoxicating liquor, the court ruled. The driver's hips and buttocks were on the driver's side of the front seat. His head and the rest of his body were slumped horizontally on the front seat and generally to the right of the driver's side. His legs and feet were near, but not on, the controls, and the motor was running. It was practically, if not wholly, impossible to conceive that any other person could have gotten into the driver's seat, manipulated the gears and driven the car to the spot where it was found, with the driver sitting as he was with relation to the driver's seat and with his legs and feet situated as they were, the court said.

Radioiodine Serum-Albumin

Blood Volume Determinations

RANDOLPH M. FERLIC, M.D.**
ROBERT D. SELLERS, M.D.**
C. WALTON LILLEHEI, M.D.**
Minneapolis, Minnesota

HISTORICALLY, BLOOD volume measurement dates back to 1853 when Lehman and Weber studied two decapitated criminals by washing out their vessels to determine the volume.[1] This, of course, is a direct method. The indirect method on which all the current techniques are based should be credited to Valentin, who in 1838 suggested that with the infusion of a known volume of water into a living animal the circulatory volume could be estimated from the resulting dilution in accordance with the following equation:

$$\text{Concentration} = \frac{\text{Quantity}}{\text{Volume}}$$

and $Q_1 = Q_2$ because the solute does not change identity

therefore, $C_1 \times V_1 = C_2 \times V_2$

$$\text{thus, } V_2 = \frac{C_1 \times V_1}{C_2}$$

Blood Volume Measurement by Tracers

In order to furnish practical information, tracers had to be developed which met the following requirements and assumptions: First, a tracer should be nontoxic, nonantigenic, and preferably inert. Second, it should be easily identified quantitatively in small concentrations. Third, its quality or volume should not appreciably affect the volume of the blood. Finally, there should be no appreciable loss of the tracer during the time required for complete mixing.

Many tracers have been utilized satisfactorily, although none meets all the above criteria perfectly. They can be separated, however, depending upon their compartmental distribution into plasma volume tracers and red-cell volume tracers.

Red-Cell Labeling

The first practical approach to red-cell labeling was by Grehant and Quinquand in 1882, when they measured the cell volume with carbon monoxide.[2] Its absorption by pigments other than hemoglobin, however, rendered the method inaccurate. The techniques which utilize radioactive labeling of the red cells with Fe_{59}, Fe_{55}, P_{32}, and Cr_{51} are all accurate. Because of its practicality Cr_{51} has been utilized most frequently. The disadvantages of cell labeling compared to plasma labeling lie in the necessity for preparation of the cells, which is time-consuming and

In 250 Cardiac Patients Undergoing Open Heart Surgery*

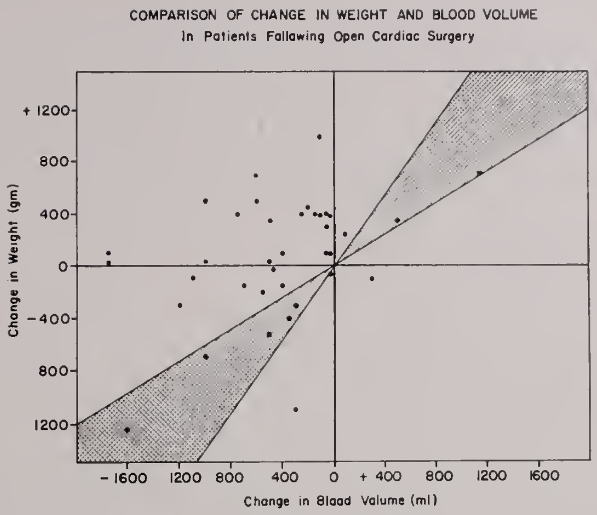

Fig. 1 — The blood volume change during operation as estimated from careful immediate pre and postoperative body weights in 38 patients was compared in the same patients to blood volume changes measured by RISA. Note that the two parameters agree in only eight instances (21%) even when a 40% range plus or minus is allowed (shaded area).

also introduces the possibilities of blood incompatibility or bacterial contamination.

Plasma Labeling

Plasma labeling utilizing dyes was initiated by Keith's use of vital red in 1915,[3] but did not reach practical popularity until the introduction by Dawson of Evans Blue (T-1824) in 1920.[4] The latter dye measures the plasma volume accurately. However, it may be unsatisfactory because hemolysis, free plasma hemoglobin, plasma turbidity, and repeated injections may interfere with the determination. The most commonly used and the most practical tag in our view has been radioiodinated human serum albumin. Seligman and Fine introduced the method of radioactive plasma labeling in 1943.[5] There are other plasma tags such as C_{14} and S_{35} which have been utilized experimentally with satisfactory results, but as yet their labeling processes are too complicated for clinical use.

The Problem

The problems posed by patients undergoing corrective cardiac surgery with extracorporeal circulation challenges the clinical judgment of the surgeon. Even with the most careful preparation, these patients sometimes represent extreme examples of physiologically poor surgical candidates. The spectrum sometimes includes patients with well compensated defects and no permanent alterations, but more frequently patients with intractable heart failure involving permanent cardiac, pulmonary, renal, and hepatic damage.

Since the respiratory, circulatory, nutritional, and excretional functions depend on adequate circulation, it is very important to know the effective blood volume available for tissue perfusion. This is particularly true for chronic illnesses with constantly changing cardiac outputs and wide volumetric alterations.

Expanded Blood Volume

Cardiac patients are in a precarious state, many having an expanded blood volume. Their poor myocardial reserve is aggravated by increased circulating catecholamines and adrenal hormones, which may not be restored to normal even after intensive medical therapy. In recent studies we have found that the preoperative levels of catecholamines are elevated in all patients with acquired heart disease in functional Class III and IV as well as in patients with congenital cyanotic heart disease.[6] Quick reflection on the physiologic responses to hypo and hypervolemia will indicate that these patients have already exhausted their first-line defenses, and even minor changes must mobilize a maximum response in order to restore homeostasis. Thus the patients' physiologic mechanisms usually require augmentation by the physician to preserve life.

Changes in Blood Volume

The weighing of these patients in the operating room before and after surgery was developed in order to allow an estimate of any changes in blood volume occurring during surgery.[7] This method was useful but proved to have many shortcomings. In 1959 we began to determine each patient's blood volume before and after surgery, utilizing dilution techniques with radioiodine-tagged human serum-albumin (RISA).

Methods

The patient is given a 4-ml. dose of radioiodine serum-albumin containing between 5 and 10 microcuries of activity after a blood sample has been drawn for background activity. An intravascular mixing period of 10 to 15 minutes is allowed and a final blood sample is drawn. A 4-cc. aliquot of each blood sample is placed in the scintillation well and counted for four minutes. The results are then compared to the previously counted standard dilution of the injected dose for that particular batch of radiodine-serum-albumin doses. The calculation is carried out as follows:

$$V_2 = \frac{C_1 \times V_1}{C_2}$$

$$V_2 = \frac{\text{Total Counts Injected - Background Counts}}{\dfrac{\text{Counts Final Sample - Patient Background}}{\text{cc. of Sample}}}$$

$$V_2 = \frac{2{,}800{,}000 \text{ Counts}}{\dfrac{2{,}800 \text{ Counts}}{4 \text{ cc.}}}$$

$$V_2 = 4{,}000 \text{ cc.}$$

Radioiodine serum-albumin's distribution and extent of dilution is taken to denote the total blood volume. The red-cell volume and plasma volume are then calculated from the hematocrit. The hematocrit, of course, is a large vessel value which can be further corrected to a total body hematocrit by multiplying it by approximately 0.91. (We do not make this correction.)[8]

In the 250 most recent cases analyzed, all patients had corrective procedures employing the pump oxygenator and a minimum of three blood volume determinations performed during their hospital stay. These were made initially a few days before surgery, immediately after surgery, in the post-anesthetic recovery room, and again on the first postoperative day.

At surgery the oxygenator was generally primed with 10% low molecular weight dextran 16-20 cc/kg. or with a dextran-mannitol combination. At the end of the corrective procedure and with the gradual return of good cardiac function, the contents of the helical reservoir were gradually pumped back into the patient.[9]

Results

Our patients were studied with carefully recorded weights immediately before and after surgery in the operating room, allowing for all the intravenous tubing, chest tubes and other paraphernalia. The weight change did not correlate well with the blood volume changes (Figure 1). From this data it may be seen that even if one allows a plus or minus 40% possibility in the weight-volume change correlation, only eight of our 38 patients showed a weight change correlating with the change in blood volume.

The preoperative blood volumes in the patients with congenital heart disease undergoing surgery are summarized in Figure 2. Figure 3 summarizes the comparable data for patients undergoing surgery for acquired cardiac disease.

The blood volume performed in the post-anesthetic recovery room usually indicated that the patient, in spite of very careful replacement of estimated blood losses, was 200-300 cc. behind his preoperative blood volume. The blood volume determinations on the first postoperative day showed almost no deviation from the preoperative values, thus confirming the inherent accuracy of the method when carefully performed.

Comments

The preoperative variation of blood volume in cc/kg. was fairly constant in those patients with both acquired and congenital disease, whether male or female. Thus the patient's lesion and/or sex did not appear to influence the blood volume as much as the cardiac disease. There appeared, however, to be some exceptions to this, in that we noted that patients with cyanotic type tetralogy of Fallot and those patients in the terminal phase from aortic or mitral valvular disease had the most elevated values. It should be emphasized that the blood volumes represented here were determined after intensive medical therapy, since they were done immediately before elective surgery.

The usual clinical formulas for estimating the effective blood volume have proved unsatisfactory in such patients. The utilizations of the height-weight formulas such as:[10]

PREDICTED BLOOD VOLUME

Men: $PBV = 0.3669 H^3$ plus $0.03219 W$ plus 0.6041
Women: $PBV = 0.3561 H^3$ plus $0.03308 W$ plus 0.1833

for blood volume estimation, seriously underestimate the blood volume in 70% of our patients. From all clinical indications these cardiac patients require their expanded blood in the early convalescent period. Thus our aim in the postoperative period was to restore the patient's volume to its preoperative levels, unless it was extremely high or unless central venous pressure was ominously elevated. Central venous pressure is certainly a valuable auxiliary tool in the postoperative management once the effective blood volume is known. But as the sole or prime determinant of volume, it may be grossly misleading, since the "normal" venous pressure for the cardiac patient may be several times the normal for noncardiacs.

One of the objections to the radioiodine-serum-albumin methods is that it fails to define the exact limits of the red-cell volume because of the shortcomings innate in hematocrit determinations. The other objection is that the distribution of radioiodine serum-albumin also includes a small portion of the extravascular compartment.[11] While conceding the theoretical validity of these objections from a practical standpoint, these errors are relatively small and are almost completely neutralized when a preoperative determination has been made, which is always possible in elective cases and nearly always possible in emergency situations, since the determination takes only 12 to 15 minutes.

Summary

Serial radioiodine serum-albumin blood volume determinations have proved reliable, accurate, and helpful in the management of over 1000 patients undergoing open cardiac surgery. Analysis of the data from 250 recent cases indicates that there is no substitution for this actual measurement.

August — Saint Roch

St. Roch (circa 1295-1327) is a noble and unforgettable figure among the saints whose commemoration dates fall in August. Historical facts about him are meager, but legend has immortalized him in a touching and heroic story of self sacrifice.

From his home in Montpelier, France, Roch set out as a young man on a pilgrimage to Rome. Journeying through northern Italy where the plague was devastating the entire area, he could not resist lingering there to care for the wretched victims, vast numbers of whom were dying either of the disease itself or of starvation before they could recover, as food, water, and nursing service became ever scarcer.

Shortly before Roch's arrival at Piacenza a small, persistent dog had attached himself to the pilgrim. During the height of the scourge, when Roch found it impossible to leave his sickest patients long enough to go out for food, the little dog Tino went instead. He had been trained to proceed to the shop of the one baker still operating on short rations in the town to pick up a small or even just a partial loaf of bread each day for his master to feed bit by bit to his numerous convalescent patients.

One day while returning to his roofless hut after his long day's ministrations, Roch himself suddenly succumbed, and, being unable to walk further, crawled into an abandoned shed on a hillside, where days later his little dog found him and saved him from imminent death by presenting him with a tiny loaf of fresh bread which he had coaxed from the baker, who later followed to the rescue.

Surely Tino's devotion to his master makes him almost as equally worthy on canonization as Roch himself; but being just a dog, he can receive only honorable mention in the annals of heroism. However, Roch and Tino are too inseparably linked for us to think of one without the other; and perhaps reflected glory shines all the more brightly.

St. Roch is also known as Roche, Rock, and Roque. His date is August 16.

Advice

"Be yourself!" is about the worst advice you can give some people.

— John Masefield

Severe, Recurrent Hypoglycemia

Due to

Chlorpropamide Therapy*

EVERETT H. KARON, M.D.**
JEROME L. KREMER, M.D.**
St. Paul, Minnesota

CHLORPROPAMIDE (DIABENESE), because of its biochemical properties, may cause severe, prolonged or occasionally recurrent hypoglycemia. Despite this possibility, only four such cases have been reported in detail in the English literature to date.[1-4] We should like to present another case and to discuss the possible mechanisms responsible for this potentially serious complication of oral hypoglycemic drug administration.

Case Report

The patient, a 40-year-old female, was first seen by one of the authors in March 1963. Her presenting complaint was referable to a recent knee injury; however, she also had noted ease of fatiguability and a 15-pound weight loss over the preceding six-month period. A routine urinalysis showed 4-plus glycosuria, and a fasting blood glucose was found to be 204 mg.%. She was started on an 1800-calorie diabetic diet and on chlorpropamide, 500 mg. each morning before breakfast. Over the next 10 days the blood sugar was gradually reduced to 109 mg.% and she regained three pounds of weight.

She was seen twice in the ensuing eight months and felt quite well. Her weight remained stable and urine-sugar tests were either negative or showed only a trace of glucose. Blood-sugar determinations were not obtained during this interval.

The evening of December 5, 1963, the patient reported intermittent numbness of the left side of her tongue and of the left hand of 12 hours' duration. Arrangements were made for her to be seen the next day. About two hours later, she again communicated with one of the authors, complaining of swelling of the left upper lip and some difficulty with her speech. She was advised to come to the hospital emergency room for evaluation at that time; however, she did not appear. The following morning, she was found to be unresponsive and was brought to the hospital emergency room.

Physical Findings

Preliminary examination revealed her to be semistuporous. Vital signs were normal. The skin was cool but not clammy. The pupils were equal in size and reacted normally to light. The eyeballs were firm. Her eyes exhibited a tendency to wander and she was unable to focus on a stationary object. Toe signs (Babinski) were positive bilaterally. The remainder of the examination revealed no abnormalities.

Response to Treatment

Blood for serum glucose determination was drawn immediately and 50 ml. of 50% dextrose solution was given intravenously. After administration of the first 40 ml., the patient became alert and coherent. It was then learned that she did not recall the previous evenings' conversations and therefore had not come to the hospital sooner. She did recall feeling hungry and said she had consumed four bananas, six English muffins and a quart of orange juice during the preceding night. This amounts to approximately 250 grams of carbohydrate. For two weeks prior to admission she had been aware of periods of extreme hunger and a craving for sweets. One week earlier, she had also experienced a disulfiram*-like reaction after ingesting a small quantity of alcohol.

---

*Read before The Minnesota Society of Internal Medicine, May 16, 1964.

**From the Department of Internal Medicine, The Charles T. Miller Hospital, St. Paul, Minnesota.

She was admitted to the hospital for further evaluation and was placed on her previous 1800-calorie diet. The initial blood-glucose level was reported as 35 mg.%. During the day, she continued to complain of intermittent, mild dizziness and a "funny feeling." A blood-glucose level an hour after the evening meal was found to be 56 mg.%, and accordingly, a generous bedtime snack was given. At 3:15 A.M., 18 hours after admission, the medical intern was called to see the patient who noted profuse sweating, shakiness and slurred speech. Another 50 ml. of 50% dextrose was administered intravenously; however, a blood glucose was not obtained. She responded promptly and four hours later the blood glucose was 99 mg.%.

No further hypoglycemic symptoms were noted throughout the remainder of her hospital stay. Subsequent fasting blood-glucose levels were 110 and 105 mg.%. To rule out the possibility of a functioning islet-cell adenoma, an intravenous Tolbutamide test was performed. The curve obtained was typical for diabetes mellitus alone.

The patient was discharged on dietary restriction, and oral hypoglycemic agents were discontinued. On December 23, 1963, her fasting blood-sugar level was 80 mg.%. On September 30, 1964, when last noted, her fasting blood sugar was still only 74 mg.% after she had been off chlorpropamide for over nine months.

Discussion

The previously reported cases of severe and prolonged hypoglycemia following chlorpropamide administration have shown many similarities to this case. In all, the duration of coma, relapse into a deep hypoglycemic state, or persistence of symptoms despite apparently adequate therapy was 24 hours or longer. The reported blood-glucose level was 35 mg.% or less in each of the cases, reaching a low of 8 mg.% in one case 24 hours after admission and early therapy.[1] Two of the patients had received an evening dose of chlorpropamide the day prior to the development of hypoglycemic coma.[1,2] One case was that of a nondiabetic male who had been given large doses of chlorpropamide (2 grams per day) for two days prior to developing a prolonged hypoglycemia.[3] He developed permanent personality and intellectual changes with an abnormal electroencephalogram. However, he exhibited laboratory evidence for chronic hepatic disease; and this fact plus the very high dosage of drug administered were probably responsible for the unfortunate outcome. The three diabetic patients had taken the drug for periods nine days to eight months before developing their difficulties. Their daily dosage was 250-500 mg. of chlorpropamide.

Side Effects of Chlorpropamide

Hypoglycemic symptoms have been reported by most authors working with this oral hypoglycemic agent. The symptoms have generally been of mild degree and respond to oral glucose administration. Upon reduction of the drug dose, such reactions tend to disappear. Other side-effects from chlorpropamide include gastrointestinal disturbances, transient neurologic symptoms (primarily ataxia), skin rashes, somnolence, muscle weakness, chest pain, disulfiram-like reactions to alcohol ingestion, agranulocytosis and cholestatic jaundice. These side-effects have been variably reported in 2-8% of patients taking the drug and are felt to be dose-related. Agranulocytosis and cholestatic jaundice, however, may be due to true drug idiosyncrasy.

Physiologic Properties

Severe and prolonged hypoglycemic reactions fortunately have been rare. They are probably due to the combination of inherent physiologic properties of chlorpropamide plus the variations of individual patient response. It is known that chlorpropamide is rapidly and completely absorbed from the intestinal tract over a two to four-hour period with the peak hypoglycemic response occurring in about 10 hours. The drug is bound to plasma proteins and is slowly excreted in the urine in a chemically unchanged form. Knauff et al. have shown the metabolic half-life to be about 35 hours compared with a four-hour half-life for tolbutamide.[5] Following 16 days of continuous administration, demonstrable serum levels of chlorpropamide may be found for an additional 20 days.[6,7] Johnson and associates have described a dual disappearance rate for chlorpropamide which has not been observed in excretion studies of the other sulfonylurea drugs.[8] In normal subjects studied, over 80% of the drug is excreted in a rapid initial phase having a metabolic half-life* of 32 hours. The remainder is slowly eliminated in a second phase having a half-life of approximately 16 days. In diabetic patients who have been on chlorpropamide therapy, the amount excreted in this latter phase may increase two or three-fold. Whether this is due to increased plasma-protein binding, drug storage, perhaps in the liver, or some other mechanism is not known.[9] The clinical significance of this finding has not been elucidated. Serum levels of chlorpropamide, following repeated doses of the drug, show a rapid, straight-line cumulative curve for several days before a plateau is reached.[7] By contrast, repeated doses of Tolbutamide cause a subtle stepwise increase in blood serum levels, and the peak levels clinically are generally lower than those seen with chlorpropamide.[10] As the degree of hypoglycemia attained is a function of serum concentration of the agent used, it can readily be seen why chlorpropamide is three to six times more potent than Tolbutamide on a dosage basis.

---

*See Test Your Word Score Page 1029.

The Possible Mode of Action

Despite extensive metabolic studies there is not complete agreement regarding the mode of action of the sulfonylurea agents in lowering blood sugar. The suggested mechanisms of action include stimulation of insulin release from beta cells, a direct effect on liver-glycogen metabolism, increased glucose uptake by skeletal muscles and inactivation of insulinase. Release of free insulin to act physiologically on the liver-glycogen stores would seem to be the probable mode of action.

Knowing the biochemical properties of chlorpropamide, one can postulate one or more of the following mechanisms to explain the appearance of the severe degree of hypoglycemia following its use in therapeutic doses: (a) simple relative overdosage of a potent hypoglycemic agent, (b) effect of cumulative high serum levels of the drug due to delayed excretion or release of stored or bound drug, (c) possible inactivation of serum insulinase at high serum levels, or (d) a normal response to a potent hypoglycemic agent following amelioration or remission of a treated, mild diabetic state.

We feel that this latter mechanism was responsible in the case presented, as the patient shows no diabetic symptoms or stigmata after cessation of drug therapy for 10 months.

Summary

A case of prolonged and recurrent hypoglycemia secondary to chlorpropamide (Diabenese) therapy occurred in a 40-year-old female patient who had previously taken the drug in the same therapeutic dosage for eight months without untoward reactions. Such severe reactions are rare, but the case is presented to alert physicians on the advisability for continued and close observation of such a patient, should a severe degree of hypoglycemia be noted.

The fingers must be educated, the thumb is born knowing. — *Chazal*

*Paleopathology II**

What do we know about the diseases that afflicted our early brothers on this planet? What have we learned from the skeletal remains of prehistoric man?

From pathological bone remnants found in caves paleopathologists have discovered that cave bears and Stone Age man shared some of the same diseases, mute but convincing evidence of the homogeneity of evolutionary organisms. Modern man's susceptibility and vulnerability as compared with his distant progenitors' are striking.

On the femur bones of Java man appear exostoses which, on the authority of the noted pathologist Virchow, significantly resemble those of modern man. Remains of Piltdown man show evidence of pathological alteration of the skull bones, with the characteristic thickening associated with acromegaly and Paget's disease. The bones of one Neanderthaler reveal a fracture of the proximal end of the left ulna. Stone Age man must have suffered numerous fractures during his strenuous existence — combatting the forces of nature, the assaults of wild animals, and the hostility of his own species. What he did about fractures is something of a mystery; however, since only three out of 18 observed fractures show poor healing, we can assume that he was probably adept at applying splints.

Other pathologies among Stone Age men, noted by paleopathologist Roy Moodie, were spondylitis deformans, scoliosis, hyperostoses, arthridites, ulcerations, atrophy, exostoses, and osteomata.

Aside from splints for fractures primitive bone surgery appears to have consisted chiefly of providing a convenient exit for the demons considered responsible for disease: particularly headache and insanity. Countless primitive skulls show evidence of trephining, a voluntary and probably sacramental surgical procedure in primitive medicine. Of 120 individuals disinterred from a French burial mound 40 (33⅓ per cent) showed trepanation of the skull, an indication that headache or pain was discouragingly prevalent among our progenitors.

Besides trepanning to exorcise disease demons cicatrization was also resorted to by early man. From the skulls involved this barbarous procedure consisted in scraping or cutting a T-shaped cicatrice on the cranium and then cauterizing it with boiling-hot oil. A less frequent and more drastic measure than trepanning, cicatrization must have been more effective in ousting demons, since no crania show evidence of a repetition, whereas some skulls show numerous trepanizations, compelling testimony of early man's physical endurance and the persistence of his symptoms.

Within the limited framework of primitive Homo's conception of his mysterious and menacing world his attitude toward and defense against accident and disease display a resourcefulness and rationale by no means to be ridiculed or denigrated by his modern descendants.

6-12 mo.	½ tsp. q.i.d. (4 mg.)
1-2 yr.	½ tsp. 5 times daily (5 mg.)
2-5 yr.	1 tsp. t.i.d. (6 mg.)
5-8 yr.	1 tsp. q.i.d. (8 mg.)
8-12 yr.	1 tsp. 5 times daily (10 mg.)
Adult	2 tsp. 5 times daily (20 mg.) (or 2 tablets q.i.d.)

*Based on 4 cc. per average teaspoonful.
Note: After diarrhea is controlled the initial dosage can usually be reduced to meet the requirements of the individual patient.

LOMOTIL® TABLETS/LIQUID

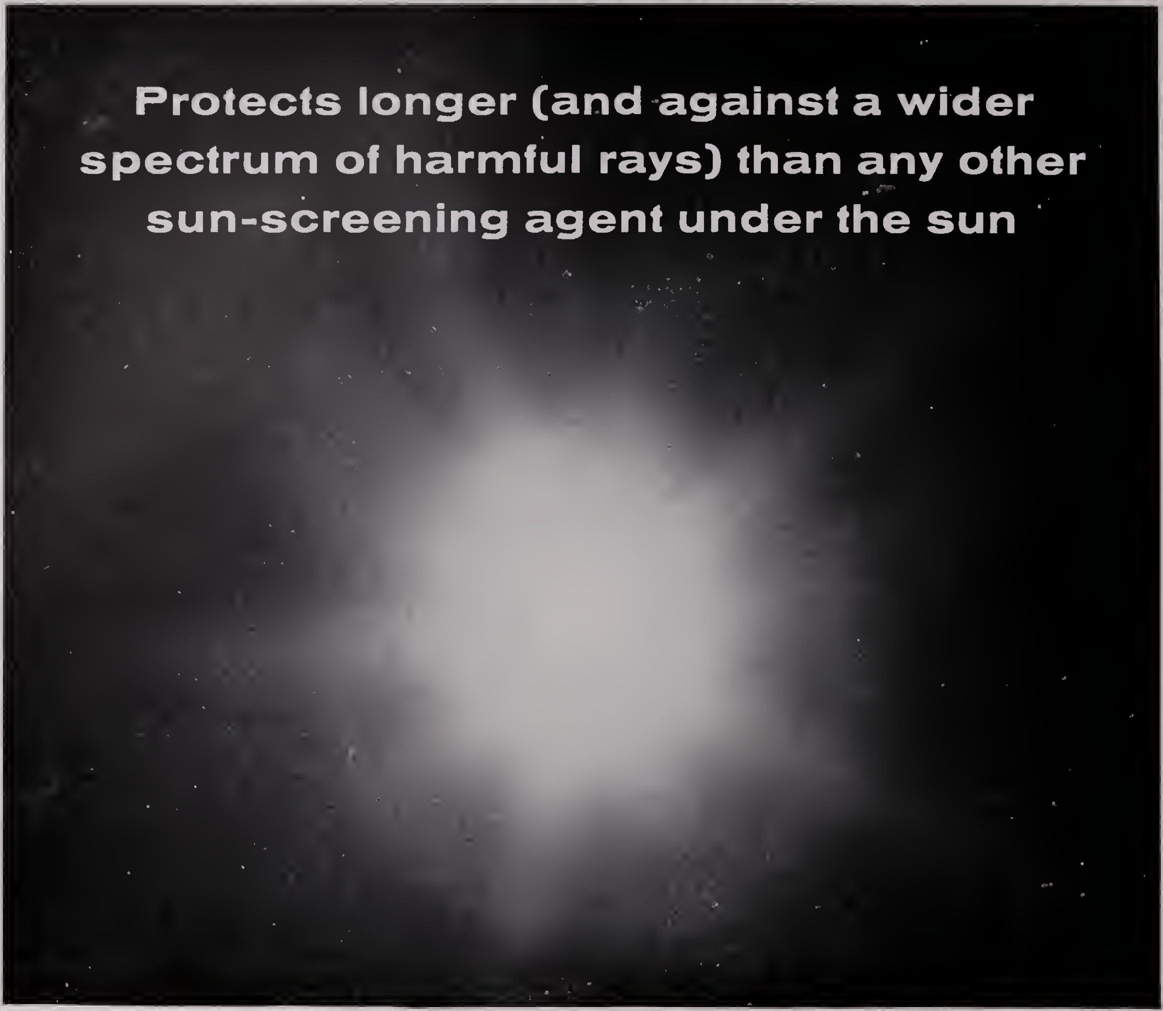
Each tablet and each 5 cc. of liquid contains:
diphenoxylate hydrochloride ....2.5 mg.
(Warning: May be habit forming)
atropine sulfate ....0.025 mg.

Precautions
Lomotil is an exempt narcotic preparation of very low addictive potential. Recommended dosages should not be exceeded. Lomotil should be used with caution in patients with impaired liver function and in patients taking addicting drugs or barbiturates.

Cautions and Side Effects
Side effects are relatively uncommon but among those reported are gastrointestinal irritation, sedation, dizziness, cutaneous manifestations, restlessness and insomnia.

Lomotil is a brand of diphenoxylate hydrochloride with atropine sulfate; the subtherapeutic amount of atropine is added to discourage deliberate overdosage.

SEARLE *Research in the Service of Medicine*



Protects longer (and against a wider spectrum of harmful rays) than any other sun-screening agent under the sun

new UVAL

ULTRA-VIOLET ABSORBING LOTION*

Clinical studies show that many drug-induced photosensitivities are initiated by solar rays longer than 3200 Å. Most commercial lotions absorb *only short, burning rays up to about 3100 Å.* New UVAL provides excellent screening of short, erythema-causing waves *and* sustains high effectiveness throughout the photosensitizing spectrum (up to 6500 Å). Moreover, laboratory studies in humans demonstrate that UVAL protects *hours longer*‡ than any other sun-screening agent available. Such protection is unprecedented. UVAL has no known contraindications and is cosmetically acceptable. Literature (including a list of photosensitizing agents) and samples available on request.

‡As long as UVAL remains on the skin

Concerning the Potassium Ion

In a June issue of Minnesota Medicine,* Snively and Westerman[1] emphasized the important role of the potassium ion in disease. This importance stems from the fact that potassium is an essential ion in numerous metabolic processes. As the principal intracellular cation it is necessary for the growth and repair of tissues. It is required for the synthesis of glycogen and appears to inhibit glycogen breakdown. By the generation of bioelectric potentials and formation of high energy phosphate bonds the potassium ion contributes to normal cardiac and neuromuscular function. The role of potassium in competing with hydrogen ion in the mechanisms concerned with the renal tubular reabsorption of sodium indicates the importance of the potassium ion in acid-base equilibrium. Moreover, potassium deficiency, even in the absence of metabolic alkalosis, is associated with a diminution in renal blood flow and glomerular filtration rate and with a pitressin-resistant defect in the renal tubular reabsorption of water. In view of the fact that all of these functional defects have their morphologic counterparts, as so well reviewed by Snively and Westerman,[1] the importance of understanding the pathophysiology of potassium deficiency by all who practice clinical medicine becomes readily apparent.

Numerous diseases and conditions which give rise to potassium depletion are summarized by Snively and Westerman.[1] In general, these may be categorized under the following three mechanisms: (1) decreased intake, (2) excessive gastrointestinal losses, (3) excessive renal losses. One might question the inclusion of the therapeutic low sodium diet, the nephrotic syndrome, and hepatic cirrhosis in this list. In those diseases in which sodium is virtually completely reabsorbed by the proximal renal tubule and renal excretion of sodium is negligible, sodium will not be available for distal renal tubular exchange for potassium; and potassium deficiency does not usually exist. Untreated congestive heart failure, decompensated hepatic cirrhosis, and the nephrotic syndrome are such diseases. Potassium diuresis may fail to occur even in the face of adrenocortical hyperfunction.[2]

For the diagnosis of a state of potassium depletion the history of a disease or a condition known to give rise to potassium deficiency is the most important single factor in diagnosis. The serum potassium concentration per se is frequently not a reliable guide to the presence or absence of potassium depletion because serum potassium levels may not accurately reflect cellular potassium concentration. Thus, in dehydrated patients the serum potassium may be elevated in the face of marked intracellular deficits of potassium. The experience with patients admitted with diabetic keto-acidosis is a classical example of this phenomenon. Prior to therapy the majority of patients with diabetic coma will demonstrate a serum potassium concentra-

On Stelazine® brand of trifluoperazine
she's calm and alert

When a tranquilizer is needed, 'Stelazine' can regulate the level of anxiety so that the patient is unlikely to overreact to stress but is not tranquilized into psychic inertia. Patients on 'Stelazine' often experience a sense of mental alertness and, because they feel so much better, are more interested in their normal activities.

Contraindicated in comatose or greatly depressed states due to CNS depressants and in cases of existing blood dyscrasias, bone marrow depression and pre-existing liver damage. *Principal side effects,* usually dose-related, may include mild skin reaction, dry mouth, insomnia, fatigue, drowsiness, dizziness and neuromuscular (extrapyramidal) reactions. Muscular weakness, anorexia, rash, lactation and blurred vision may also be observed. Blood dyscrasias and jaundice have been extremely rare. Use with caution in patients with impaired cardiovascular systems.

Before prescribing, see SK&F product Prescribing Information.

Photograph professionally posed.

SK&F

Smith Kline & French Laboratories

tion of 5-6 meq./L. Marked hypopotassemia may occur some 6 to 12 hours after insulin and parenteral fluid therapy have been initiated. Moreover, serum potassium is known to vary with the pH of blood — being high in metabolic acidosis and low in metabolic alkalosis. In patients with metabolic acidosis the shift of potassium from intracellular to extracellular fluid may maintain a normal or elevated serum potassium in spite of intracellular depletion of potassium.

A word of caution is indicated in two important aspects of the treatment of patients with potassium depletion. It is still not clear whether the functional changes of potassium deficiency are due to the loss of potassium intracellularly, to the secondary gain of sodium intracellularly, or to intracellular acidosis. There is, however, ample experimental evidence[3] indicating that high sodium intakes are lethal to potassium-depleted rats. This evidence, together with the fact that sodium may increase the urinary excretion of potassium, indicates that sodium-containing fluids should be given judiciously to the potassium-deficient patient. It is common for many clinicians to order parenteral saline and/or glucose solutions as initial fluid therapy. Solutions of glucose may also be associated with immediate deleterious effects in a patient with potassium depletion by accentuating the extracellular potassium deficit.

Finally, it may be noted that there are many problems to be solved in the understanding of this important ion. What is the mechanism of the functional and morphologic changes associated with potassium depletion? Does potassium deficiency lead to irreversible renal damage? Is the susceptibility to pyelonephritis increased? These and many more questions remain to be answered in the future.

Pity the Unfortunate Patient with Hypertension Today

WITH THE gradual identification of secondary forms of hypertension, a profusion of diagnostic tests has resulted, for which each patient is a potential candidate. The excellent series of articles published in this journal mention only a few that have been developed with reference to the diagnosis of renal artery disease. Whole batteries of tests to exclude renal parenchymal, endocrine, or anatomic causes of blood-pressure elevation have also been developed in recent years. Many of these tests are time-consuming, uncomfortable, and rather expensive.

The better understanding of high blood pressure that these newer tests offer is valuable; but the vast majority of hypertensive patients have only essential hypertension. Therefore, it is particularly important that the physician originally evaluating the patient consider the severity of the blood-pressure elevation, the age of the patient, and any associated diseases before embarking on extensive diagnostic procedures. There is extreme need to carefully consider the real value of a given test to a patient and whether he, as an individual, will ultimately benefit from the procedure.

The ultimate object of these diagnostic tests is to determine the most satisfactory method of treating the patient. Although it is exciting to find increasing numbers of patients with renal arterial stenotic lesions, pheochromocytomas, or aldosterone-producing tumors, at the present time the physician should continue to approach the therapy of essential hypertension with the same zeal that he approaches the diagnosis of these rare secondary forms of hypertension.

Butazolidin®
brand of
phenylbutazone

in osteoarthritis

Geigy

Therapeutic effects
A number of investigators report improvement in about 75% of cases. Relief of pain and stiffness is the predominant response. Frequently, there is also a significant improvement in function. The beneficial effects of the drug are usually seen by the third or fourth day of treatment.

There is general agreement that milder cases of osteoarthritis are preferably treated by simple analgesics. In many patients, however, this mode of therapy fails to give sufficient relief. Because steroids are not very effective in this form of arthritis, phenylbutazone affords the drug therapy most capable of relieving the more severe cases. For best results, it is recommended that treatment with phenylbutazone be combined with physiotherapy and other appropriate supportive measures.

Dosage
The initial daily dosage in adults is 300-600 mg. in divided daily doses. In most instances, 400 mg. daily is sufficient for maximum therapeutic response. A trial period of one week is adequate to determine the effects of the drug; if there is no improvement, discontinue the drug. When improvement does occur, dosage should be promptly decreased to the minimum effective level: this should not exceed 400 mg. daily, and is often achieved with only 100-200 mg. daily.

Precautions
Before prescribing, the physician should obtain a detailed history and perform a complete physical and laboratory examination, including a blood count. The patient should be kept under close supervision and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools. Regular blood counts should be made. The drug should be used with greater care in the elderly.

Warning: If coumarin-type anticoagulants are given simultaneously, the physician should watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea and sulfonamide-type agents and insulin. Patients receiving such concomitant therapy should be carefully observed for this effect.

Side effects
The most common side effects are nausea, edema and drug rash. Infrequently, agranulocytosis, generalized allergic reaction, stomatitis, salivary gland enlargement, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia are also possible side effects. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently.

Contraindications
These include: edema, hypertension, or danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. Because of the increased possibility of toxic reactions, the drug should not be given when the patient cannot be seen regularly, when the patient is senile, or when other potent chemotherapeutic agents are given concurrently. Large doses of Butazolidin® alka are contraindicated in patients with glaucoma.

Note: The physician should be fully aware of dosage, precautions, side effects and contraindications as contained in the complete prescribing information.

Butazolidin alka

Each capsule contains:	
Butazolidin, brand of phenylbutazone	100 mg.
dried aluminum hydroxide gel	100 mg.
magnesium trisilicate	150 mg.
homatropine methylbromide	1.25 mg.

The Case for Cholecystostomy

PERHAPS NO clinical entity has been so obscured by folklore and half-hearted investigation as cholecystitis.

Descriptions of the histologic changes remain much as detailed by Aschoff. The exact sequence and nature of the tissue changes and disturbance of function are still not clear: hence a variety of controversial opinions about them. As a result, the treatment of the disease has been for the most part empirical.

We know that patients have gallstones and that as a result of foreign-body reaction with or without the interaction of pancreatic reflux and/or bacteria, inflammatory changes develop.

In a few instances acute cholecystitis results. This, if allowed to follow an uninterrupted course, usually results in a return to the status quo or in the so-called hydrops. In a few instances the gallbladder becomes gangrenous and ruptures. Bile peritonitis may result; but unlike the rupture of an appendix or other intraperitoneal appendages, suppurative peritonitis rarely follows.

The obvious procedure is to remove the gallbladder before this stage is reached. For numerous reasons this may be deemed inadvisable and, as an alternative, cholecystostomy is performed.

This prevents the liberation of bile into the peritoneal cavity but does little if anything to mitigate the disease of the gallbladder. Unfortunately, a certain number of patients die — not from gallbladder disease *per se* but because of the trauma of surgery and anesthesia or from some unrelated disease process.

If this number is large, as may be noted in the published series, the question naturally arises as to whether or not cholecystostomy is a reasonable procedure.

It is difficult to find a report of any considerable number of untreated cases of acute cholecystitis which have progressed to gangrene and rupture and have terminated fatally.

In contrast there are many published series of cholecystostomies which have an average mean mortality of 20%. Because of the many variables involved, the statistical material may not be conclusive; but the great disparity between the mortality of cholecystostomy and that of untreated acute cholecystitis contributes to the belief that with few exceptions cholecystostomy is an indefensible procedure. In short, if the mortality in acute cholecystitis cannot be kept within a 5% limit by cholecystostomy, other means should be employed.

Collapsing Hip Nail*

THE REPORT by Dr. Harris* and his associates relating to the experience at the Hennepin County General Hospital (with the collapsing hip nail) emphasizes, and rightly so, *accurate reduction* in anatomic or slight valgus position, *locking* of the medial trabeculae of the femoral neck, and *compression* of the fracture site. The authors imply that their good results — and they are good results — may be due in part to the use of the Massie collapsing nail. Granting that a collapsing or telescoping nail is of no real advantage in intertrochanteric fractures, its use in intracapsular fractures has been discussed and debated in recent years. It has its proponents, and Dr. Harris and his associates appear to be of this group.

The sliding nail purportedly does not "hold the fracture apart" or allow migration of the nail through the head into the acetabulum. Actually, any flanged nail used in fixation of femoral neck fractures will tend to slide laterally and to protrude from the femoral cortex if and when absorption of the fracture site occurs, providing the nail is not fixed to the lateral cortex of the femur with

plate or screw. Thus, in subcapsular and transcervical fractures, the ordinary flanged nail, unfixed to the lateral cortex, "slides" by protruding from the lateral cortex, and allows the fracture ends to stay in apposition. There may be some advantage in the sliding nail in basilar fracture where one does fix the nail to the lateral cortex — providing that the nail truly does slide. The Massie nail, like other collapsing nails, is a mechanical device and sometimes does not perform in vivo as it is alleged to.

To prove whether the Massie collapsing nail is better than any other type of fixation would necessitate groups of patients treated comparably (except for the internal fixation device). It would be helpful if Dr. Harris and his associates had such a group or groups for controls.

Proper reduction, impaction, and co-operation of the patient postoperatively would seem to be the important factors in the healing of a fractured femoral neck. The type and method of internal fixation may not be so important. It has even been said that if reduction, impaction, and co-operation by the patient are satisfactory, fixation can be maintained with a "wet noodle." While this may be carrying the concept too far, it does make the point.

**Depend on low-cost,
low-dosage Prolixin
—once-a-day**

Prolixin is a dependable tranquilizer that provides your patient with low cost therapy. No other tranquilizer costs less. Safe and convenient for office use—Prolixin in a single daily dose provides prolonged and sustained action. Markedly low in toxicity and virtually free from usual sedative effects—Prolixin is indicated for patients who must be alert. Clinical experience indicates fluphenazine hydrochloride is especially effective in controlling the symptoms of anxiety and tension complicating somatic disorders such as premenstrual tension, menopause, or hypertension—also useful for anxiety and tension due to environmental or emotional stress. When you prescribe Prolixin you offer your patient effective tranquilization that is low in cost, low in dosage and low in sedative activity.

THE SQUIBB TRANQUILIZER

WHEN TRANQUILIZATION WITHOUT SEDATION IS DESIRABLE, TRY

PROLIXIN®

SQUIBB FLUPHENAZINE HYDROCHLORIDE

SIDE EFFECTS, PRECAUTIONS, CONTRAINDICATIONS: As used for anxiety and tension, side effects are unlikely. Reversible extrapyramidal reactions may develop occasionally. In higher doses for psychotic disorders, patients may experience excessive drowsiness, visual blurring, dizziness, insomnia (rare), allergic skin reactions, nausea, anorexia, salivation, edema, perspiration, dry mouth, polyuria, hypotension. Jaundice has been exceedingly rare. Photo-sensitivity has not been reported. Blood dyscrasias occur with phenothiazines; routine blood counts are recommended. If symptoms of upper respiratory infection occur, discontinue the drug and institute appropriate treatment. Do not use epinephrine for hypotension which may appear in patients on large doses undergoing surgery. Effects of atropine may be potentiated. Do not use with high doses of hypnotics or in patients with subcortical brain damage. Use cautiously in convulsive disorders.

AVAILABLE: 1 mg. tablets. Bottles of 50 and 500.

Breast Cancer

BREAST CANCER arises from a primary focus in that organ in the great majority of instances. Ordinarily it begins as a small lesion. If it is less than one centimeter in diameter the incidence of metastases will be 40 per cent or less; sixty to 70 per cent of these small carcinomas will not have metastasized to the axilla. Five-year cure rates obtained in individuals without axillary metastases may be as high as 80 per cent. With axillary involvement even in highly selected series of cases this figure drops to 40 per cent and may be considerably lower.

The most skilled and experienced examining hand cannot identify the tiny tumor as benign or malignant with any degree of regularity or certainty. In the patient whose potential for cure is greatest the question of whether the suspected area differs from the surrounding breast tissue is often hard to answer. In any but the most superficially placed tumors the classical signs of breast cancer are the signs of well established disease. In actuality the earliest clinical manifestation of breast cancer is a minute and all but imperceptible change in consistency of a small area of the breast. Biopsy under these circumstances will often be negative; yet there is no other way to identify the small cancer most amenable to therapy.

A recent article in Minnesota Medicine* discussing radiographic breast examination stated that seven of 10 breast cancers can be diagnosed by clinical examination.* To accept this statement as a basis for practice renders a great disservice to women: it means that breast cancer is being neglected until there is an excellent chance that it is no longer confined to the breast. Attempts at cure under those circumstances by any therapeutic means or combination thereof is most likely to result in failure.

Confusion and contrary opinion may exist in the approach to the treatment of breast cancer; yet the inescapable fact remains that therapy directed toward the lesion which is still confined to the breast offers much. It is our duty as physicians to use the tools that we have — crude though they may be — in the most effective way. First and foremost among them is surgical biopsy of all suspicious areas in the breast.

The theory that biopsy should be carried out only when a "dominant" lump is identified allows many small cancers to become large. After such tumors have reached seven centimeters or more, axillary metastases alone are present in 80 per cent; tumors of such size are not infrequently seen in surgical practice today. Small wonder that a segment of lay opinion fears "cutting a cancer."

Physical examination of the breast is not easy. Normal variation is great. The large, dependent, mobile breast defies palpatory identification of small tumors deep in its substance. In these and other selected cases roentgenographic examination may be a helpful adjunct. New modalities may successfully probe the breast and refine our diagnostic skill. Any woman of reasonable intelligence, armed with proper knowledge, can learn to examine her breasts with accuracy in regard to early change. With concise instruction as to ovulatory function and periodic change secondary to hormonal ebb and flow, mystery and fear of the unknown can be replaced with knowledge. Frequently this will result in bringing breast tumors to the physician's attention at a time when they can readily be cured. It is appalling to note that on the average 10 months or more elapses from the time the patient is first aware of symptoms (usually a lump 80+%) before she presents for definitive treatment.

The efficacy of early identification of small breast cancers followed by prompt surgical treatment cannot be disputed. Let us not fail the woman who presents with an early change in the breast.

Until our imperfect understanding of this dreadful common illness improves, those trite words EARLY DIAGNOSIS constitute our most effective approach to this problem.

to help relieve pain in common anorectal disorders

"non-caine" Diothane®

Diothane—with its chemically distinct "non-caine" anesthetic agent diperodon—provides effective temporary topical anesthetic and emollient actions for soothing relief of anorectal pain. Anesthetic activity is effective and relatively prolonged; sensitization is infrequent. Reports to Merrell on 1,500 patients treated pre- and postoperatively with Diothane Ointment, indicate only 22 developed local skin reactions. Reactions to Diothane have been burning or stinging sensations and a few cases of allergic manifestations. An additional advantage: Diothane Ointment and Suppositories are mildly antiseptic. Prescribe or recommend either form...both are now available.

DIOTHANE OINTMENT

COMPOSITION:
diperodon 1.0%; oxyquinoline benzoate 0.1% in a special ointment base.

INDICATIONS:
Provides temporary palliation of pain that may result from hemorrhoidectomy and from common anorectal disorders such as hemorrhoids, anal fissures, pruritus ani.

DIOTHANE®
OINTMENT
Relief
CHILL
PULL APART

DIOTHANE SUPPOSITORIES

COMPOSITION:
Each suppository, weighing approximately 2.6 Gm., contains diperodon 1.0%; urea 10.0%; oxyquinoline benzoate 0.1% in a special hydrophilic suppository base. A unique shape keeps the suppository in intimate contact with mucous membranes.

INDICATIONS:
Provide for temporary palliation of pain caused by hemorrhoids and pruritus ani.

THE WM. S. MERRELL COMPANY
Division of Richardson-Merrell Inc.
Cincinnati, Ohio 45215/Weston, Ontario

Letter to the Editor:

Dr. Arnold Kremen* has done it again. The caduceus is *not* our "symbol of medicine," modern or otherwise, and it does *not* have "a serpent" wrapped around it. It is the emblem of the messenger god, Mercury, who inherited the functions of the Greek Hermes, who had in turn inherited the functions of the Babylonian messenger god, Ningishzida. The emblem of all three was and is a *pair* of snakes, intertwined in coitus, symbolic of the creation of new life in the springtime in response to the message borne to all living things by the sacred messenger. The caduceus had, and has, nothing to do with medicine.

The staff "wrapped" or entwined by a single serpent is the emblem not of Mercury but of Aesculapius or Asklepios, the Greek (and, by loan, Roman) god of medicine. This staff was a proper walking staff or cane — not a rod of office or scepter as in the case of Hermes and Mercury — so that the gold-headed cane, or any cane, is indeed appropriate to a physician.

The Editor's Soliloquy

Eschew that Cliche

There is almost nothing more devastatingly disarming than the cliche: that hackneyed, stereotyped expression that somehow catches the fancy of the unthinking vulgus.

Eric Partridge, British authority, both raises and answers the question as to why cliches are so popular and so extensively used. He says: "An uncultured little-reading person sees a stock phrase and thinks it apt and smart." So it catches on!

Many cliches were originally vivid and striking linguistic *tours de force,* which by overuse became superannuated. As our American authority, H. L. Mencken, put it: "Many an apt and ingenious neologism, by falling too quickly into the gaping maw of the proletariat, is spoiled forthwith and forever."

Legion are those who believe they are injecting verve and vigor into their vernacuiar with a profuse spattering of such expletives as: "Says you!" "I'll tell the world!" "Alrightie!" "You can say that again!" Though these trite expressions make us wince a bit, we wryly accept them for their hearty buoyancy and artlessness.

Slightly more irritating is the pseudoscientific cliche with its aura of authority and irrefutability. This category includes the sympathy-compelling neomedical cliche which flows so officiously from the mouths of assorted hypochondriacs et al. and is calculated to endow its utterer with a halo of special dispensation for his strep throat, his slipped disc, his toxic bowel, his tired blood, or his whiplash injury. This individual's nerves are astonishingly volatile and versatile: they can be frayed, pinched, shot;

MINNESOTA'S LARGEST MEDICAL-SURGICAL PLAN
2344 NICOLLET AVE. • MINNEAPOLIS, MINN. 55404

or he can be a bundle of them! Whatever his distinctive lament, his ego is thereby vastly inflated.

Even more annoying is the individual with a flair for the foreign cliche, the unfamiliarity of which seems to deny its commonness and belie its platitudinousness — thereby setting up a snob appeal from which few dare demur. To the discomfiture of his listeners he embellishes his conversation with unexpected and startling *bete noirs* and *alfrescos.* Myriad are the atrociously mispronounced French and Italian terms that issue glibly from the mouths of the linguistically pretentious who wish to humble their peers and awe the unthinking masses who delight to sit in the shadow of the more sophisticated.

The category of personally-directed cliches covers a wide spectrum. At one end is the purely affectionate, back-slapping "You old son of a gun!" Next comes the disarming, chuckle-producing label designed to insinuate subtle contumely without incurring liability or arousing resentment: 'absent-minded' or 'long-haired professor,' 'pill-dispenser,' 'head-shrinker,' 'saw-bones,' etc. These slightly barbed sobriquets provide a convenient weapon for 'slaying' friend or foe alike with complete immunity from reprisal and are deliberately used by the invidious who wish to humiliate or derogate their superiors.

The snide term 'egghead' is employed by the secretly envious to disparage the individual with a high I.Q., who may have attained recognition for academic achievement, and who declines to look, act and sound plebian and scorns to adopt the mucker pose.

The reprehensible character-slashing cliche is that unsubstantiated but ex-cathedra announcement that so-and-so is an 'extremist,' an 'atheist,' a 'communist,' an 'anarchist,' or some other 'ist' — no less sinister and subversive. These are the most indefensible and unpardonable of the pejoratives, because they are too often fatally damaging to the reputation of the victim to whom they become attached.

The press and other news media are notorious for their exploitation of cliches, especially in the heat of political controversy or war hysteria. For example — when one's enemy makes a coup, military diction terms it a 'sneak attack'; but a coup achieved by one's own consecrated forces is a 'surprise attack,' or is even highly touted as a stroke of 'brilliant strategy.' Such stereotypes are avidly seized upon by the undiscriminating and gullible, to be perpetuated in the argot of headline history that shapes public opinion and so determines foreign policy.

Excepted and omitted from our repertoire are many immortal phrases: the March of Time, the Patience of Job, and the Sword of Damocles — which can be used indefinitely without losing luster and power; they are classics without which our language would be the poorer and meaner.

Whether condoned or condemned, however, cliches as a generality give us a "pain in the neck." Oops!

APACHE
APACHE COMPLEX

You've Made Us Change

APACHE MEDICAL COMPLEX

We started with plans for the most modern, most efficient, most tenant-oriented *medium-sized* medical complex in Minnesota. Your response forced us to change our plans. Now we're going to construct the most modern, most efficient, most tenant-oriented *large-sized* medical complex in Minnesota, to be built at Apache Plaza in two medium-sized stages. Stage 1, pictured above, will be ready for you in Spring, 1966.

Here are some of the reasons why Apache Medical Complex will be the ideal location for your new office:

- Ample free parking for everyone, reserved parking for doctors.
- Convenient for patients and staff, part of a 60-store shopping complex.
- Handy to Twin Cities hospitals.
- Attractive, dignified building, giving you the best professional address north of either loop.
- Complete facilities, including pathology and radiology laboratories.
- Essential ancillary services and shops.
- Restaurant facilities conveniently located for doctors, patients and staff.
- Modern building techniques will give total flexibility to your office space-planning.

APACHE MEDICAL COMPLEX

Curbstone Consultation

Ionizing Radiation

QUESTION: Have any drugs been developed which actually afford protection against ionizing radiation?

ANSWER: Some experiments have shown that radiation damage may be mediated through radiation-produced decomposition of water within the tissues. However, an adverse effect on vital cell molecules results from these highly reactive decomposition products of water, a fact which suggests attainment of protection through development of a chemical agent that can "intercept" these breakdown products of water.

Anoxia has been observed to increase survival rates in experimental animals, suggesting the use of drugs which create tissue anoxia through a variety of mechanisms.

Following irradiation to a target molecule there can result loss of a hydrogen atom, with the formation of a radical on that molecule. This radical may react with oxygen to form peroxidases, to decompose, or to cross link with other molecules. Chemical agents which could serve as hydrogen donors, it is postulated, might neutralize these very reactive radicals.

Thiols have been found to be more sensitive to radiation than disulfides. There is hope, therefore, that the critical thiol group may be shielded by being bound in a mixed disulfide linkage with a protector molecule.

Some of the more promising agents tried to date include aminothiols and their disulfides (e.g., cysteine, cysteamine, mercaptoethylguanidine), amines (e.g., histamine), dithiocarbamates, cyanide and organic nitriles (e.g., potassium cyanide), and others (e.g., steroids).

Most of the promising work has been done on experimental animals. Results showing protection by a dose-reduction factor of 1.5 are common. Improvement in results is also being sought through use of a combination of drugs by which it is hoped that the therapeutic effects will be additive, while the toxic effects will not be.

Talking is a hydrant in the yard and writing is a faucet upstairs in the house. Opening the first takes all the pressure off the second. — Robert Frost

Miltown®

An eminent role in medical practice

- Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.
- The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.

Indications: 'Miltown' (meprobamate) is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, 'Miltown' fosters normal sleep through both its anti-anxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of pre-existing symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Miltown®
(meprobamate)

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: In two strengths: 400 mg. scored tablets and 200 mg. coated tablets.

Before prescribing, consult package circular.

Fracture–Trauma Conference

—Trapped Fibula—

An Injury of the Ankle Which Requires Open Reduction of the Fibula

Many fractures and fracture dislocations occur in various parts of the skeletal system which are not reducible to their anatomical position because of soft tissue interposition or other unusual characteristics of the skeletal injury itself, such as the presence of intra-articular fragments. The posterior tibial tendon, peroneal tendons, ligamentous tissue and periosteum are examples of structures which are often found to prevent the anatomical reduction of skeletal injuries of the ankle.

There is an infrequent injury to the ankle which has not been widely reported and is often misdiagnosed and mistreated. Beware of this injury! It is one in which the proximal portion of the fibula has been displaced and trapped behind the posterolateral ridge of the tibia. This can occur in either a bimalleolar fracture-dislocation or subluxation of the ankle, or bimalleolar or trimalleolar fracture without a subluxation or dislocation. In some cases a subluxation or dislocation of the talus has occurred but is reduced by the patient or ambulance attendant by the time x-rays are taken and the physician sees the patient.

The mechanism for this injury is not clear. As the leg rotates upon the foot, the intact fibula may be pulled posteriorly behind the tibia by the lateral collateral ligaments and interosseous membrane. In the mechanism of this injury the talus is rotated posteriorly from under the tibia, causing further stress on the lateral collateral ligaments, which eventually leads to the fracture of the fibula against the posterior tibial border. The proximal fibular fracture thus becomes "locked" in this position.

It has not been definitely explained why the proximal fibular fragment becomes locked. Bosworth felt that it was held in this position by the tight stress of the interosseous membrane above the fracture site.[1] The author of this article has attempted to reproduce this injury in a number of cadavers. It is his opinion that there are three possible factors involved in maintaining the posterior displacement of the proximal fibula: (1) tight stress of the interosseous membrane; (2) entrapment into the interosseous membrane and/or other soft tissue structures at the posterior aspect of the tibia; (3) and the most important, the displacement of the proximal fragment anteromedially to the distal fragment so as to become locked by the distal fragment.

Case Report

The patient is a 17-year-old white female, who while walking her dog stepped off the

Continued

curbing, sustaining an injury to her right ankle. She was taken to the emergency room, where the house physician noted a deformity of the ankle, which represented either a subluxation or a dislocation of the ankle joint. In order to make the patient more comfortable while waiting for her private physician, he manipulated the ankle and reported that the deformity became reduced. Subsequent x-rays revealed a bimalleolar fracture of the ankle. She was taken to surgery and under general anesthesia her ankle was manipulated and placed in a plaster cast. Post-reduction x-rays left some doubt in the physician's mind as to his reduction. Further consultation was then obtained, the cast was removed and the ankle remanipulated. The second post-manipulation films revealed that the proximal fibular fragment had not changed its position (Fig. 1). Also noted was an unusual, double transverse fracture through the medial malleolus. The patient's ankle was then prepared for open reduction. A posterolateral skin incision was made over the fractured fibula, and the proximal fibular shaft was found to be locked in back of the posterolateral ridge of the tibia. A pereosteal elevator was placed over the anterior aspect of the shaft of the fibula and by considerable pressure applied posteromedially and then laterally; the fibular shaft was freed and the two fragments fell into an anatomical position. A biocortical screw was then placed across the fractured fragments. Attention was next directed toward the medial malleolus fracture; two Kirschner wires were placed across the fracture fragments (Fig. 2-a, 2-b). The patient has been followed routinely since surgery and has made satisfactory progress.

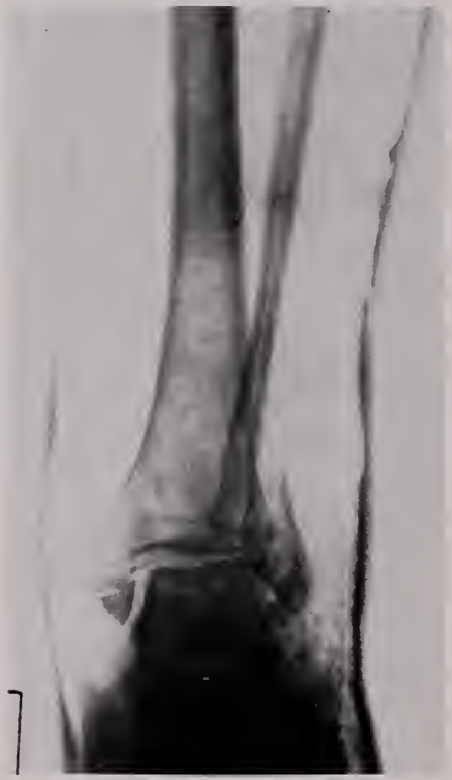

Figure 1

Discussion

This injury will become more apparent after an attempt at closed reduction is made and post-reduction films show that the position of the proximal fibula has not been changed. Do not be misled into believing that the x-rays taken were not truly anteroposterior or lateral views. On the anteroposterior view the proximal fibula can be readily seen to be displaced posteriorly and medially (Fig. 1). This will be confirmed on a lateral x-ray.

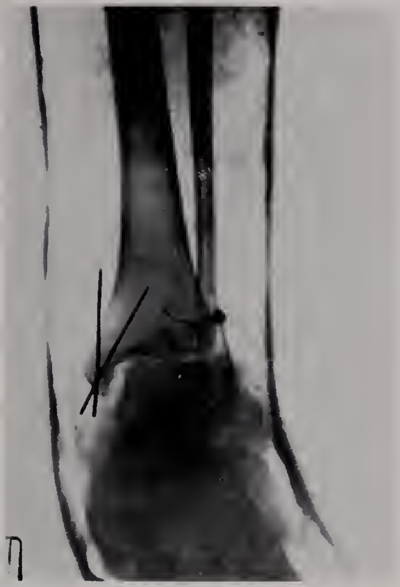

Fig. 2-a

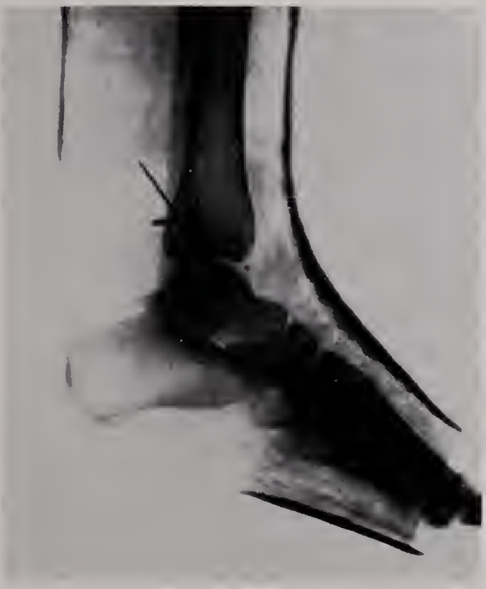

Fig. 2-b

The treatment of this injury in nearly all of the cases reported has been open reduction and internal fixation. As mentioned earlier, this injury may include a dislocation or subluxation of the talus in addition to the fracture. In such cases the talus usually cannot be completely reduced until the fibular fracture is reduced because of the traction-like attachments of the soft tissues from the displaced fibula to the talus and calcaneus. However, like most extremity fractures, an attempt at closed reduction should be made. This is done by placing the fingers on the fibular shaft and applying pressure posteriorly and laterally while inverting the ankle. If unsuccessful, an open reduction should be done. The fibular fracture is usually oblique and is in an anteroposterior plane. A posterolateral incision over the fracture site with a bicortical screw for fixation is recommended (Fig. 2-a). Following the reduction of the fibula fracture, attention should be directed toward proper treatment of the remaining components of this injury. This may require open or closed reduction, depending on the involvement of the talus and fractured tibia (Fig. 2-b).

After Surgery: B and C vitamins are therapy

Therapeutic amounts of B and C in stress formula vitamins often are vital during periods of physiologic stress. STRESSCAPS, designed to meet increased metabolic demands, aids in achieving a more comfortable convalescence, a more rapid recovery. After surgery, as in many stress conditions, STRESSCAPS vitamins are therapy.

Each capsule contains:

Vitamin B_1 (Thiamine Mononitrate)	10 mg.
Vitamin B_2 (Riboflavin)	10 mg.
Niacinamide	100 mg.
Vitamin C (Ascorbic Acid)	300 mg.
Vitamin B_6 (Pyridoxine HCl)	2 mg.
Vitamin B_{12} Crystalline	4 mcgm.
Calcium Pantothenate	20 mg.

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

Carcinoma of the Lung — A Rare Disguise

Carcinoma of the lung usually presents as a mass visible on chest x-ray. Frequently associated atelectasis or pneumonitis may be the predominant presenting sign. Occasionally we may see irregular cavitation within a large carcinoma as it outgrows its blood supply. It is rare that a small carcinoma will cavitate to present as a thin-walled peripheral cavity. Such a case is here presented.

Case Report

This man was 59 years old when he consulted his physician for a routine physical examination and advice about his bilateral inguinal hernias. The hernias had been present for a number of years and apparently had caused little discomfort. However, approximately three months earlier, he had taken a job which required more physical exertion than he had been formerly accustomed to. Associated with this increased activity, he had noted aching in the lower abdomen. He was asymptomatic as regards his chest. There was no known exposure to anyone with chest disease. He had not traveled beyond Chicago and Milwaukee. He smoked one and one-half packs of cigarettes each day.

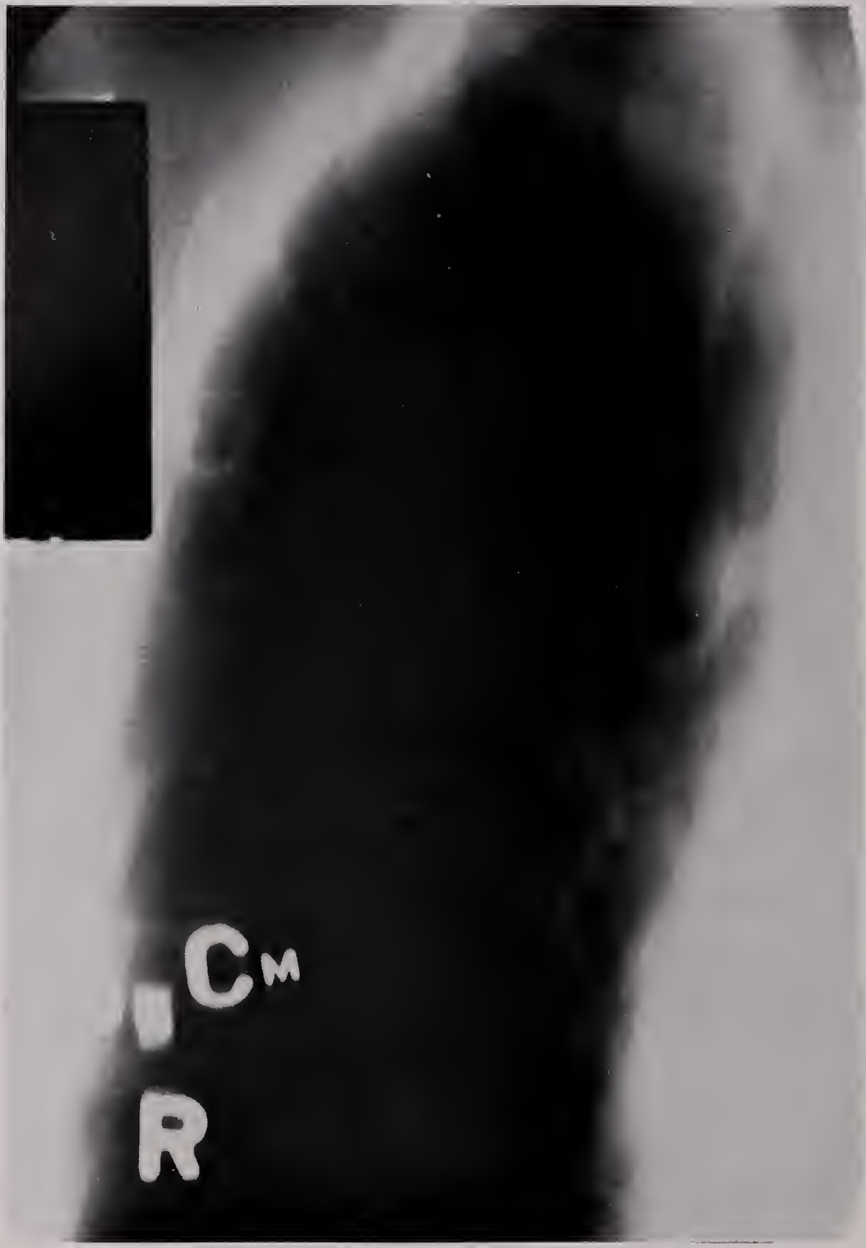
Physical Findings

Physical examination revealed a well developed, slightly obese 59-year-old male who was alert, cooperative, and did not appear ill. The blood pressure was 126/88. The remainder of his physical examination was entirely normal except for the following pertinent or positive findings. There were upper and lower dentures. There was no cervical adenopathy. The lungs were normal on physical examination except that the breath sounds were somewhat distant. Examination of the heart was normal. There were large bilateral inguinal hernias.

Laboratory Findings

Laboratory studies revealed the urinalysis to be normal. The hemoglobin was 15.2 gm. per cent. The white blood cell count was 7,590, of which 58% were neutrophils, 39% lymphocytes and 3% monocytes. The erythrocyte sedimentation rate was 57 mm. fall in one hour. The blood urea nitrogen was 12 mg.%. An electrocardiogram was normal. Seven sputa were negative for acid-fast bacilli and fungus on smear, and subsequently these were negative also on culture. Five gastric washing specimens were negative for acid-fast bacilli on smear and culture. Several sputa for tumor cells were negative. The skin test and complement fixation for coccidioidomycosis was negative. The tuberculin skin test showed over 2 cm. of induration. Chest x-ray on April 6, 1964, was normal except for a thin-walled ring like shadow in the right upper lobe at the level of the right second anterior space. This measured approximately 1.2 cm. in diameter. Planograms of this area revealed a thin-walled cavitary lesion best seen at the 10.5 cm. level.

Continued



Thin-walled cavitary lesion

It is our practice in the interest of avoiding postoperative complications to require that our patients be off smoking for at least two weeks before surgery. This patient was discharged to spend this period at home. Because of the possibility that the cavitary lesion was due to tuberculosis he received Isoniazid 300 mg. and P.A.S. 12 grams daily. He returned to the hospital and a right thoracotomy was performed. The cavitary lesion seen on x-ray was excised by scissors dissection and reported by the pathologist to show a very poorly differentiated carcinoma. A right upper lobe lobectomy and mediastinal node dissection was then performed. On his final report, the pathologist confirmed his frozen section diagnosis and suggested that the tumor most resembled a squamous cell type. Thirty-six nodes were examined and none showed evidence of metastasis. The postoperative course was uneventful. He subsequently has had repair of his inguinal hernias and to this date continues to be well and free of recurrence of his bronchogenic carcinoma.

Comments

Fanned by the high winds of modern sales techniques using every available medium to promote the use of cigarettes, an epidemic of lung cancer is raging across this land. Approximately 45,000 people, many at the peak of their most productive period, will die of carcinoma of the lung this year. Each year this number will increase to follow the rise in cigarette consumption. Until the general population is sufficiently enlightened to avoid cigarette smoking or until we understand the biology of cancer, our only defense is early diagnosis and adequate surgery. Early diagnosis will depend upon recognizing the enemy in each of its many disguises as readily as we do when it presents its usual appearance. The small thin-walled peripheral cavity which was this patient's bronchogenic carcinoma is a relatively rare disguise. The alertness and prompt action of his medical doctor fortunately lead to an early surgical attack with reasonable hope for cure.

This case is presented for the purpose of emphasizing the treachery of this disease and to publicize one of its less common disguises.

TRISOMY 13-15 (ALSO CALLED D TRISOMY) SYNDROME*

It has not been possible to establish whether the trisomy involves chromosome 13, 14, or 15; thus it is usually referred to as Group D Trisomy. This condition has been found in a number of newborn infants.

The cases are usually characterized by the following clinical symptoms: anophthalmia, cleft palate, harelip, polydactyly. The hands show horizontal palmar creases and relatively slim terminal phalanges with unusually convex fingernails. The thumbs can be bent backwards to an abnormal degree, sometimes referred to as "Trigger Thumb" (a better description might be "retroflexibility").

There may also be hemangiomata over the body and appendages, congenital heart defects, mental retardation, and early death.

Lee Schacht, M.D.
Minneapolis, Minnesota

TRISOMY 16-18 (ALSO CALLED GROUP E TRISOMY) SYNDROME*

It is fairly well established that this is a trisomy of chromosome 18. While this condition was thought originally to be very rare, with a full clinical description and chromosome analysis now available, it may be frequent as Trisomy 21 (Mongolism).

This disease is characterized by the following clinical description: ear deformities — low set, and sometimes malformed; spasticity due to a central nervous system defect; "Rocker Bottom" feet — an abnormal backward extension of the heel; flexion deformity of the fingers — the index finger over the middle finger when the fist is closed; micrognathia, umbilical hernia, congenital heart defects and failure to thrive — rarely surviving more than a few months.

Lee Schacht, M.D.
Minneapolis, Minnesota

Hepatolenticular Degeneration*

Mentation —

Dr. Robert Soll: Hepatolenticular degeneration is a relatively rare hereditary disease appearing approximately once in 50,000 live births, an incidence similar to such heritable diseases as phenylketonuria. Our case today concerns a 26-year-old man with hepatolenticular degeneration.

Dr. L. R. Ringhofer:* In March 1964, I was called to the patient's home by distressed parents who told me that their son had lost consciousness. By the time I arrived, the patient had awakened, although he was somewhat groggy and had difficulty standing. I felt that he was having a post-seizure confusional state, and therefore I admitted him to the hospital for observation. As the patient's mental state gradually cleared, I was able to obtain a better history from him.

He is a young man who has been under the care of numerous doctors in recent years. His main concern was a shakiness of his hands, beginning at the approximate time of his divorce three years previously. In view of that history and a completely normal neurological examination except for a persistent mild tremor, I thought his trouble was probably more functional than organic. Only a year before another physician who had given him a complete workup in the hospital, had reached the same conclusion. At that time the patient had been placed on a tranquilizer which he had continued to take until the time of his unconscious episode.

Dr. Soll: Other than loss of consciousness and subsequent confusion, was there any other evidence that this may have been a seizure?

Dr. Ringhofer: There were no focal neurological findings. I was looking, of course, for a focal abnormality, but I found nothing except confusion and some unsteadiness when standing. The possibility that these might be functional or deliberate also occurred to me.

Dr. Soll: Did his parents witness the spell?

Dr. Ringhofer: Yes, it happened while he was taking a drink of water. Apparently he toppled over backwards in front of everybody. When he

The pediatric conferences are held the first and third Wednesdays of every month from 3:15 to 4:15 p.m. The adult conferences are held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Charles Branthaver, in Pediatrics, and Dr. Robert Soll, in Adult Neurology. Conference held December 3, 1964.

*New Ulm, Minnesota physician.

Continued

didn't respond, they called me. The entire episode lasted about 15 or 20 minutes. By the time I arrived, he was sitting on the floor.

Mrs. Lora Lee Ruthenbeck:* We have known the patient ever since his admission to the St. Peter Hospital where he spent several months prior to his divorce in 1961. His marriage had been shaky from its beginning in 1958. He did not do well after his discharge.

Dr. Ringhofer: According to our clinic records, in 1959 the patient was noted to be withdrawing, negative and tense; psychiatric help was suggested then, but it was refused. Interestingly, on the occasion of his premarital examination in 1957, something about his general attitude must have been unusual, since the doctor whom he was seeing then advised him against marriage. This particular aspect of the history also fit with the idea of a functional type of problem. An intensification of these symptoms apparently lead to his admission to the State Hospital.

Dr. Joe Rich:** I first saw the patient on June 24, 1964, in New Medicine Clinic; he related essentially the same history to me as has been presented. Initially, I also felt that his problems were psychologically based. Apparently his hand tremors had increased markedly after his divorce, but then remained unchanged for six months before his visits here. On physical examination he had a wild flapping tremor of both arms and legs, worsened by any attempt to make an intentional movement. Also the tremor persisted when the patient was left alone by himself in the examining room: a fact which put my first impression on a somewhat shaky basis. The patient seemed to lose his balance very easily when standing or walking. Otherwise our initial neurological examination was not very decisive, since there were no other abnormal manifestations noted. Subsequently in Neurology Clinic, the Kayser-Fleischer rings in the cornea were noted and the tentative diagnosis of Wilson's disease was established.

The patient was admitted to the hospital on June 28, 1964. His serum ceruloplasmin† level was very low, varying from 9 to 12 units. The normal value for comparison has a range of 100 to 300 units.

Other liver function studies included a thymol turbidity — 3 units, a cephalin flocculation — 4 plus, and a BSP — 16% retention. The serum copper was less than 10 micrograms % and the urine copper was 0.056 mg./liter.

The patient was started on penicillamine, an oral chelating agent, in an attempt to increase his urinary excretion of copper. The initial dosage was 250 mg. four times daily, but it was eventually increased to 5 grams daily since an adequate increase in urinary copper was not obtained at lower dosages. In addition to penicillamine, a low copper diet, potassium sulfide and pyridoxine were also instituted. His first hospitalization extended from June 28th to August 11th, 1964. He was to return for a follow-up visit the last week in August, but he developed recurrent generalized seizures, which seemed to be more localized in his right upper extremity, and he therefore was readmitted to the hospital on September 5, 1964. After dilantin medication was instituted he had no further seizures. His tremors are diminished and there appears to be a decrease of the Kayser-Fleischer ring in the cornea.

---

*County welfare department, Brown County.

**Student doctor, University of Minnesota Medical Center.

†An A^2 blue globulin having to do with copper metabolism.

Dr. John Brantner:[*] When I saw the patient he could not be tested for brain damage, nor could he take the multiphasic by himself. The method of having someone read it to a patient is of dubious value. The Peabody Picture Vocabulary test, requiring selecting from a number of pictures the one which is most appropriate to given words, suggested a firm IQ of 108, and the Binet vocabulary test, which requires word definition, indicated an IQ of 109; therefore, I think that we can say at the present time that his intelligence is approximately 110, the upper end of the average range of intelligence. As far as his personality is concerned there are, in the Binet vocabulary test, a few hints of some personality deviation: a slightly schizoid or near schizophrenic habit of thought. He seemed to be mildly depressed, but this is certainly understandable on the basis of his disorder.

His discharge diagnosis from St. Peter where he had electroshock therapy was schizophrenic reaction, acute undifferentiated type, but the reports do not give the results of their psychological tests. He told me that he had looked at his IQ when the examiners were out of the room, and his own idea is that his IQ is 167. He feels that he is an intelligent person and that his present IQ may represent some decline. I have no means of knowing, since there are no indications of central nervous system involvement in my testing. At the present time I can only report that he is of average intelligence, but with some tendency towards schizoid mentation.[**]

Miss Helen Kretchmer:[†] I saw the patient and his mother this morning. The mother has accompanied her son on other clinic appointments, since she felt a little reluctant to have him travel alone. Apparently there is a feeling of family solidarity. The father is a retired plasterer, 73 years old, on Social Security; the mother is somewhat younger and a housewife. There are only two children, the patient and his sister, age 36, who works as a bookkeeper. The patient related that he had been a polio patient at the Sister Kenny Institute when he was a child. The family lives in a home with two bedrooms upstairs and three rooms downstairs. When he first returned home from the hospital he had to sleep downstairs because he couldn't make the stairs, as there are some architectural barriers. A wheelchair was required when he was in the hospital, but now there seem to be no particular problems at home, since he is walking by himself. The family income consists of the father's social security, the patient's social security and the sister's earnings. The patient receives $103.00 social security, out of which he pays his family $50.00 for board and room, and about $6.00 for maintaining an insurance policy; he also spends $25.00 of his income for medication. I believe the welfare board authorized the rest of the hospital care here and helps to pay the remainder of the medical bill at home, assisting them with transportation when necessary.

I assume he is eligible for aid to the disabled, which could help cover medical expenses. There is a problem about which both the family and welfare board are concerned. Each penicillamine refill costs $22.50 and lasts only five days; the cost for this alone during the month is $135.00. There are some other expenses, but they are less significant. If he is going to be cared for regularly at this hospital, he may be able to get much of his

Continued

medication here, thereby using the county authorization to split the cost between the county and the state.

The patient said that he had 10 month's trial working experience at the rehabilitation center in Mankato following his 13-month hospitalization at St. Peter, mostly shoveling snow, mowing, and doing janitorial type work. This would indicate to me that they felt from their tests and from their experience with him that his potential was not too high. Apparently he was not placed in a job after that time. He has had an occasional day at work since then, one day as a truck driver and once with a garbage collector; that is about all.

When you mention his former wife or child, both he and his mother become distressed. His marriage was an extremely unhappy experience, and the family seems to think that it may have caused his illness.

As far as the present illness is concerned, the patient feels that he is better. He can dress himself except for buttons; also he can light a cigarette and hold it while he is smoking, which he couldn't do before. He is raising two rabbits now and hopes to raise more. Activities using large muscles are performed best, although he tires easily and his foot is unstable. Regarding amusement, I called the physical therapist and she suggested his using playing card holders which he can get through a commercial company. This would enable the patient to participate with the family when they play cards. He hasn't been very hopeful; but I think he and the family would welcome some type of occupational suggestion, either vocational rehabilitation or some type of home activity. Promoting this rabbit business or some other kind of work would give him some spending money.

Dr. Soll: Mrs. Ruthenbeck, how does your concept of the patient compare with this?

Mrs. Ruthenbeck: The family have always been very co-operative and appreciative people. I have just one question: if he continues to progress physically, should there be a change in the home situation; that is, should he be encouraged to go someplace else? I tried to talk to him about this, but I wasn't very influential with him. There is a great dependency upon the mother, who is very dominating with both the husband and the son. The patient is too dependent upon her; however, during the present illness he needed someone else to help him.

Dr. Soll:

Two fairly distinct categories of patients having hepatolenticular degeneration have been described.[1]

Pseudosclerosis

One type was described by Westphal in 1883 and was termed "pseudosclerosis." Its onset usually occurs between 19 and 35 years of age and is characterized by a slowly progressive course. Chief difficulties are dysarthria and tremor with very little dystonic fixity of posture. A patient may also have cirrhotic liver disease as evidenced by a positive thymol turbidity or cephalin flocculation, but usually there are no symptoms referable to hepatic involvement until late in the disease when ascites may appear.

Progressive Lenticular Degeneration

In 1913, Wilson described the second form of this disease which he called "progressive lenticular degeneration." This type has a much earlier onset, usually between seven and 15 years of age, and is characterized by dystonia with very abnormal postures as the first sign. There may be rapid finger tremors; but the often described "wing flapping" occurs late if at all. At times myoclonic jerking may be seen. Hepatic symptoms likewise may be noted in the patient or in his family. The terminal picture in this type of the disease is one in which the limbs are rigidly semiflexed. The course, as a rule, is quite irregular with sudden severe relapses; response to therapy is poor, and survival is often less than four years. This picture contrasts considerably with those patients having the pseudosclerotic type of Wilson's disease, not only in the clinical picture, but their response to treatment is also much better in pseudosclerosis. Survival tends to be longer in pseudosclerosis and many patients have been reported to live 10 to 15 years after onset of symptoms.

I believe our patient falls into the category of pseudosclerosis, and therefore his prognosis would be much better than in the progressive lenticular degeneration type. Even in pseudosclerosis the prognosis is not the best, but he may continue to live a fairly comfortable life for several years. In view of this, I believe the patient could continue to live with his parents until such time as he is no longer physically or mentally competent.

Dr. Milton Alter:* The disorder is now established as a recessive trait, which means that the affected individual is a product of parents both of whom are carriers of the trait. The fact that our patient is affected is evidence that both parents must be carriers.

Ceruloplasmin

Exactly what is inherited here is not known, but a feature which has been found in almost all case studies is a low to absent level of a certain protein in the body called ceruloplasmin, which means literally 'blue protein.' This is a protein manufactured by the liver, the function of which is to bind copper absorbed from the intestinal tract. All of us need a certain amount of copper in our metabolism, and the regulation of the level of copper in the body is largely a function of this particular protein. It is a situation analogous to iron; iron is needed for a number of functions in the body. The situation with copper metabolism is similar in that we absorb a certain amount of copper from the diet. Initially this copper is bound to albumin. This is a very transient binding, and the copper is then released to enter various metabolic pathways. Some of it is bound by ceruloplasmin, which is a much stronger and more permanent binding for most of the copper in our body. If we have inherited the inability to make ceruloplasmin or if we have inherited defective ceruloplasmin which doesn't function properly, then our copper metabolism is abnormal. In this abnormal state, copper is first bound to albumin, but is then released and deposited in tissues where it should not be.

Lenticular Degeneration

The basal ganglia of the brain where the lenticular nucleus is located is one of the tissues where copper is deposited in this disturbed copper metabolism; hence the name "lenticular degeneration." This is thought to be the basis of the abnormal movements observed clinically. Copper is also

---

*Instructor, department of neurology, University of Minnesota Medical Center.

Continued

deposited in excessive amounts in the liver, probably causing the cirrhosis which is so common in this disorder. There is also an excess amount of copper in the kidney, which poisons enzymes necessary for renal tubular reabsorption of various substances; hence, people with Wilson's disease will spill amino acids into the urine because they can't retain them. Glucose metabolism is impaired. There is an excess excretion of uric acid and copper, and phosphorus metabolism is also handled in an abnormal way, presumably because of the poisoning of the renal enzymes. This gives rise to a whole host of problems other than the brain and liver problem which we have already mentioned.

Kayser-Fleischer Ring

Copper is also deposited in the cornea of the eye, forming a ring of pigmentation which was described by Kayser and Fleischer; the ring is named after them, the Kayser-Fleischer ring, and it is not found in any other condition. It is not present in all patients; but if it is present, it is considered pathognomonic of the condition. An analysis shows that the pigmentation in this ring is, in fact, copper. So the basic defect is a deficiency of the copper-binding protein, ceruloplasmin; consequently, the individual with Wilson's disease cannot handle copper properly.

Carriers

This patient has had a son, and the question arises: could he be affected? The answer is probably no, because the condition is so rare that it is unlikely that the patient married another carrier. The child might be a carrier but will not be affected by the disease. In carriers that have been studied, lower than normal amounts of ceruloplasmin have been found. Unfortunately some people who are not carriers also have rather low amounts of this protein. Thus, there is not a clear-cut demarcation, but on the average, carriers will show a lower amount of ceruloplasmin than the normal individual. This is probably due to the fact that one of the chromosomes in carriers can direct the production of ceruloplasmin, while the homologous chromosome cannot.

Actually, there are three genetic possibilities in this family. One fourth of the children of carriers may be entirely normal; one half may be carriers and not manifest the disease except on chemical analysis of the ceruloplasmin level, and one fourth may be affected. The likelihood in the sister's case is that she is not merely a carrier but is affected with the disorder.

In a study of fingerprints of those having this condition there is a characteristic deviation from normal in the fingerprint pattern in that patients have a excess number of whorls. Basically, there are three types of patterns: loops, arches and whorls. The normal frequency of whorls is about 30% and a high proportion of the people with Wilson's disease have an excess of whorls. This happens to be true in the patient and in the sister. Nine out of ten of the patterns were whorls in the sister; she had even more whorls than the patient.

Provocative Test

The clinical diagnosis may be aided by finding an excessive amount of copper in the urine. Sometimes this isn't found even in a known case. However, if penicillamine is given to these individuals, a release of the copper occurs which may then be detected in the urine. Penicillamine administration can be of diagnostic help as a provocative test. In a normal individual penicillamine will not cause excessive amounts of copper to be excreted.

Dr. Soll:

There are at least two schools of thought on this disease as far as treatment is concerned. On the one hand, Scheinberg[2] from the Albert Einstein Hospital in New York is quite enthusiastic about treating the patient with chelating agents such as penicillamine. He feels that this is extremely important and should be used in all patients, even to the extent of screening young children for the disease in much the same manner as is being done for phenylketonuria. He would maintain that if the disease is found early in life, much of the neurological deficit due to copper deposition in the tissues would be prevented or at least delayed. On the other hand, Denny-Brown from Boston was quite pessimistic about the prognosis of the disease even with treatment. He felt that not all patients responded favorably, particularly that group which has progressive lenticular degeneration. Patients with predominantly tremor responded best, whereas those with dystonia were benefited very little if at all. Brown also cited several instances in which episodes of hepatitis produced a clinical picture not unlike the dystonic type of Wilson's disease, but without any abnormality in copper metabolism. Because of these facts he felt that there was also some other factor involved besides abnormality in copper metabolism itself.

Dr. Alter: I am familiar with both schools of thought and with the opinion that therapy may not really alter the course of the disease very much. I personally have seen about six cases of this condition. I recall most vividly a young girl who was treated with penicillamine; she declined exceedingly fast and died of liver failure about a year after the diagnosis was made. I myself am rather pessimistic about the long term outlook for these people. However, research may well uncover a means of helping patients with Wilson's disease and we should certainly be hopeful.

Dr. Rich: The patient's sister has been tested and she has also been found to have evidence of the disease. Her laboratory data include the following: cephalin flocculation — 4 plus; serum ceruloplasmin — 13 units; and serum copper — 22 micrograms %. Although these tests are abnormal, she has very few neurological manifestations. Tremor has been noted, but it is not present at all times; some mental changes have been evident.

Dr. Soll: A very important question is: how effective is the treatment? If it really delays onset of the clinical symptoms as well as reducing symptoms already present, siblings of those who have the disease should be evaluated for treatment. Dr. Blain has been considering this problem and I'd like to ask his opinion on what he thinks should be done with the patient's sister.

Dr. Gilles Blain:* First of all, I would like to be optimistic. Many patients who have been treated with chelating agents such as BAL (British Anti-Lewisite) or penicillamine were definitely improved, and statistically, their

---

*Medical fellow specialist, neurology, University of Minnesota Medical Center.

Continued

longevity was increased, when compared to untreated individuals. So I don't think that we can say that penicillamine only improves the symptoms without increasing the longevity. It appears that it really may do both. As far as the family is concerned, the sister is involved with the disease and before we start her therapy we want to hospitalize her to obtain some base-line studies. We would also like to study the parents if possible in order to find out more about the carrier state.

Further Studies

We propose to do a liver scan, using a radioactive copper with a short half-life of about 12 hours. We would also like to further study the psychometrics, particularly in the patient and in his sister, as well as give them the battery of tests we use for our patients with vascular disease. We have done a tryptophan loading on the patient already, before he received penicillamine, during penicillamine therapy and during penicillamine and pyridoxine therapy. The reason for this is that tryptophan is involved along with B6 metabolism and one form, L- penicillamine, apparently does depress the metabolism of B6. This came up very abnormal, both during the controls as well as during the loading with tryptophan and B6. We want to repeat this on the whole family to determine if there is any abnormality. This could be due to a block in the metabolic pathway of tryptophan, or it could also be due to damage from the copper as was mentioned by Dr. Alter.

Dr. Soll: I'd like to mention the toxicities that may occur. These should be checked for frequently when penicillamine is first instituted. Rash, fever, and lymphadenopathy are perhaps the most common complications. An iron deficiency anemia may develop since penicillamine will combine with metals other than copper, but this can be corrected by simply supplying additional iron to the diet. More rare complications include skin dryness, nausea, purpuric and sometimes vesicular hemorrhagic lesions. Cataracts have been noted to appear during the course of therapy in a few patients. Renal nephrosis has also been seen which tends to improve if penicillamine is discontinued. Because of these various complications, early during the course of penicillamine therapy frequent blood counts and urinalysis should be obtained, and the patient himself should be closely observed.

The entire outline of treatment should include a low copper diet, aiming at a total copper intake of less than one milligram per day. Penicillamine may be started at 1.0 gm. daily in divided doses, and then gradually increased until the urinary copper excretion exceeds 1.0 mg./day. Doses of penicillamine greater than 4.0-5.0 gm. daily usually to not increase further copper excretion. To supplement the low copper diet, potassium sulfide is administered with meals in order to bind copper present in the food before it is absorbed into the body. In this way we attempt to maintain a negative copper balance. Pyridoxine may be supplemented in the diet because of the possibility of interference in its function by penicillamine.

Conclusions

1. The patient should continue living at home and, with the help of social welfare and vocational rehabilitation, he should be encouraged to pursue a simple occupational project.

2. Treatment of the patient's sister should be instituted in an attempt to prolong the appearance of neurological complications in her.
3. An attempt should be made to obtain as many of the previous psychological tests as possible, and further psychological testing should be made periodically in the future in order to evaluate fully any significant deterioration in the patient's mentation. This will also help to assess the effects of the penicillamine therapy on the course of the disease.
4. Regular urinary copper determinations should be done in order to maintain the penicillamine at optimal dosage; this will help keep cost of medication at a minimum level.

Silphium

Rating high in ancient pharmacopoeias was the herb drug silphium. Just what silphium was is undetermined, as pharmacologists have been unable to identify it with any of our modern plants or herbs; but its phenomenal use in ancient times is a matter of record. Its efficacy against malaria, toothache, rabies, tuberculosis, pleurisy, jaundice, sore throat, whooping cough, and miscellaneous wounds was attested to by Dioscorides, Pliny, Hippocrates, Galen and Celsus. Notwithstanding the endorsement of such notables, the modern world remains justifiably sceptical of such therapeutic versatility for any drug.

However, the demand for silphium was so great that fortunes were amassed by enterprising individuals with sufficient foresight and acumen to monopolize the supply and manipulate the market. Julius Caesar is reputed to have become such a silphium capitalist. Also one Hamuel, doctor and priest in ancient Egypt, is said to have profited handsomely by trafficking in silphium imported from Lybia — unbeknown to the custom officials.

Speculation on the identity of silphium suggests that it may have been a plant similar to laserwort or frankincense — used for fumigation and in embalming; or it may have been the prosaic asafetida, an herb with a garlic-like odor and taste, sometimes employed medicinally as an antispasmodic, especially by some sects, one of which in their excessive prudery preferred to call it rumpafetida.

But whatever silphium was, it could not have been the wonder drug it was purported to be. Had it been such, its loss to posterity would have been an irreparable one.

Sanborn's new Patient Monitoring Modules adapt perfectly to expanding intensive-care needs

Sanborn "Series 780" Patient Monitoring Systems alert the intensive-care staff *instantly* to the distress of any monitored patient, permitting more effective care of *all* patients by the available nurses.

Design of the systems in functional modules offers greatest flexibility in adapting any monitoring system to future needs — the hospital system can begin modestly and grow steadily, with original modules fully utilized in the expanding system. Also, monitoring capabilities can be quickly shifted from bed to bed, as needed. Separate modules for heart rate (with integral pacer if desired), for temperature and respiration rate, and for systolic and diastolic pressures. Other modules for synchronized defibrillation, for resuscitative cardiac pacing, for oscilloscope display of cardiac or pulse waveforms, and for automatic pacing and ECG recording with any cardiac distress. Series 780 also includes remote alarm indicators (specific-parameter or general alarms, by bed) and remote patient-select pushbutton switchboxes for through-switching of patient signals to numerical display, oscilloscope, and/or chart recorders at the central station.

A complete range of transducers, recorders, and data displays engineered by Sanborn allows us to design, install, and fully warrant the complete system required for unexcelled patient care in your hospital.

For details, phone your local Hewlett-Packard/Sanborn office or write Sanborn Division, Waltham, Mass. 02154. In Europe, write Hewlett-Packard S.A., 54 Route des Acacias, Geneva, Switzerland.

Surgical Treatment of Obesity*

There are many reports of survival after massive small bowel resections performed because of infarction and neoplasm.[1,3,8,11,13] A number of studies have been made of the amount and level of small bowel resected and the resulting nutritional status of patients and experimental animals. These studies have produced a better understanding of the small intestine and the permissible limits of resection, and stimulated the consideration of surgical bypass of the small bowel as a means of treating extreme obesity.

Weight Loss Following Small Bowel Resection

Kremen et al.[1] studied dogs divided into five groups, three animals in each group, and reported the following results:

In Group I, animals who had the proximal 50% of small bowel removed from intestinal continuity had lost 15% of their preoperative weight at seven weeks, but by 24 weeks had regained their normal weight. After 24 weeks these same animals had, in addition to their previous resection, an ileocecal valve bypass performed without significant change in their normal weight.

Group II consisted of animals who had the distal 50% of small bowel bypassed, from 3 cm. proximal to the ileocecal valve extending cephalad. These animals exhibited progressive weight loss equal to 15% of their body weight by 15 weeks postoperatively and stabilized at this weight for the following nine weeks. At 24 weeks the distal 50% of bowel was returned to intestinal continuity and the proximal 50% removed. They gradually regained weight and in 14 weeks were back to their original weight.

Group III animals were similar to Group II except that the ileocecal valve was bypassed. This group lost weight steadily and exhibited the most profound cachexia of all the groups, showing no tendency towards

Continued

compensation or stability. These animals then had the ileocecal valve replaced into continuity. Only one animal survived this second procedure, but consequently stopped losing weight.

Group IV had the proximal 70% of small bowel removed. This group lost about 5 % of their preoperative weight and stabilized at this level.

Group V had the distal 70% of small bowel removed and consequently lost about 20% of their preoperative weight and stabilized at this level without any apparent ill effects.

Levin et al.[4] studied a 42-year-old, 192-lb. white woman who had 237 cm. of small intestine from distal duodenum to within eight inches of ileocecal valve removed for a tumor. The remaining duodenum was anastomosed to the terminal ileum. Three months after the operation she was having two to four yellow, steatorrheic stools per day. Two years later her weight was about 93 lbs. and remained at about this level for the succeeding four years.

Weckesser et al.[10] in a study on animals with two thirds of their proximal small bowel removed found a 14% weight loss at five weeks postoperatively with stabilization at about 15 weeks with 24% weight lost.

Fat, Nitrogen and Water Balance Studies Following Resection

In Kremen's study[1] those animals in which the distal small bowel was diverted from the intestinal stream had a consistently high loss of fat in the stools. In groups where the proximal small bowel was out of intestinal continuity and the distal small bowel in place, the fecal fat losses were only slightly above control values. Bypass of the ileocecal valve did not appear to alter the efficiency of fat absorption in groups with the proximal small bowel removed. Similarly, in groups with the distal bowel resected and also ileocecal valve bypass no significant added effect on fat absorption was noted. No important increases in fecal nitrogen loss over control levels were observed where the proximal small bowel was removed, whereas moderate but significant increases in fecal nitrogen excretion occurred with diversion of the distal small bowel.

Fecal balance studies on 25 patients with small bowel resection were carried out by Kalser et al.[3] These resections were performed for a variety of reasons: adhesions and obstructions, gangrene and chronic inflammatory intestinal disease.

The patients were classified into groups on the basis of the extent of small bowel resected or bypassed and type of anastomosis used: Group I: six patients with less than two feet of small bowel resected; Group II: 14 cases with three or more feet of distal small bowel and adjacent colon resected so that the terminal ileum and ileocecal valve were removed; Group III: five cases with seven to nine feet of small bowel removed, but a segment of terminal ileum varying from 10 inches to two feet and the ileoceal valve and the colon undisturbed (Table 1).

These investigators[3] concluded that resection of two feet or less of ileum did not result in significant steatorrhea, but extensive resection of small bowel did result in marked steatorrhea. In those patients with a segment of terminal ileum and the ileocecal valve intact, the fecal fat was only one third as high.

Kreman et al. concluded that 50-70% of proximal small intestine of dogs can be removed with no apparent ill effects. Weight is maintained and protein and fat absorption are not significantly altered. Sacrifice of the distal

50% of small intestine produces a profound interference with fat absorption associated with weight loss. The ileocecal valve appears to have an important effect on the nutritional adjustment to sacrifice of the distal small bowel, but appears less important in sacrifice of the proximal small bowel.

TABLE I
Fecal Balance Studies[3]

Group	Wet Weight of Stools Average	Range	Fat Average	Range	Nitrogen Average	Range
	gm/day		gm/day		gm/day	
I	760	250-1800	5.7	2.4-14.2*	3.0	1.0-5.8
II	1500	420-6500	42.8	8-97	6.8	2.6-10
III	240	120-300	11.6	8.0-15.0	2.2	1.3-3.0

*Normal fat excretion in four of six cases of Group I. All in Group II and II were abnormal.

Serum Cholesterol, Lipoprotein, Plasma-Free Fatty Acids and Carotene Concentration after Small Bowel Resection

Two obese female patients were studied to determine the effect of decreasing the absorptive area of the small intestine on concentrations of serum cholesterol, lipoproteins, plasma free fatty acids and carotene.[7] Two to three years after removal of all but about 15-20 inches of jejunum with jejuno-colic anastomosis, their body weights were stable at about 90 lbs. less than preoperative levels. Serum cholesterol and beta-lipoprotein concentrations were sharply decreased to less than 50% of preoperative levels. A normal increase in concentration of plasma-free fatty acids occurred with fasting. The serum protein pattern was not changed as a result of operation.

Anemia after Small Bowel Resection

A severe megaloblastic anemia* with hemoglobin concentrations ranging from 3.8 to 7.3 gm. occurred in five of 14 cases with extensive resections of the small bowel and ileocecal valve.[3] The onset of anemia was 18 to 66 months after surgery. It was concluded that the ileum was more concerned with vitamin B_{12} absorption than the jejunum.

In Weckesser's study[10] seven of 12 animals developed anemia several months after a two-thirds resection of small bowel. In all cases this was a hypochromic anemia. Macrocytosis was not observed.

Compensatory Mechanisms

Butler[6] has pointed out that after small bowel resection, the remaining bowel increases in size and thickness to expand the absorptive surface and the patient loses weight, so that there are reduced caloric and protein requirements, and finally intestinillization of the colon occurs to compensate for the loss of absorptive surface. He claims there is a large factor of safety in the amount of available absorptive surface of the small intestine and only one half of the available absorptive surface is required. If less than one half of small bowel is lost, no compensatory mechanisms are required. If the loss is greater, compensatory changes can be anticipated.

---

Continued

Amount of Small Bowel Safely Removable

From the experience of Weckesser et al.[13] and others, it can be concluded that the response to resection of small bowel is quite variable. Many factors, such as health, age of the patient and health of the remaining segment of the intestine, are important. It appears that distal resections of the small bowel are less well tolerated than proximal resections. In general resections of 20-50% are well tolerated and many patients do well after greater percentages removed.

Sullens[16] states that 50% of small bowel can be sacrificed without persistent untoward effects, but that after removal of 75%, inanition and eventual death usually result. Resections of proximal bowel are generally better tolerated than resections of the distal bowel.

Clinical Summary

A 30-year-old white female had been followed for problems of uncontrolled obesity since age eight. A variety of diets had been tried but had failed to control her weight. She was admitted to the Mount Sinai Hospital Medical Service on 11-16-64, at which time her weight was 386 lbs. and her height 5′5″.

Past history revealed known moderate hypertension since a toxemia pregnancy 10 years before. She had had a tonsillectomy but no other surgery.

Laboratory studies revealed a normal blood urea nitrogen, creatinine 0.9 mg%, uric acid 6.2 mg%, total serum protein 7.5 mg% with 4.2 mg% albumin and 3.3 mg% globulin. Cholesterol 243 mg%. Normal hemogram and urinalysis. CO_2 29 mEq./L., chlorides 102 mEq./L., sodium 136 mEq./L., potassium 4.2 mEq./L., calcium 8.7 mg%. Bromsulphalein liver function test showed 4% dye retention at 45 minutes. Fasting blood sugar was 130 mg%. Alkaline phosphatase was 4 K.A. units. Serum carotene was 157 mcg% (normal 50-300 mcg%). Thyroid function studies were normal.

A cholecystogram was normal, as were a chest x-ray and an electrocardiogram. Studies of adrenal cortical function, including urinary excretion of 17-hydroxycorticoids and 17-ketosteroids, and response to ACTH were normal.

On November 27, 1964, surgery on the small intestine was performed as treatment for the extreme obesity. The length of the entire small bowel was 14 feet. The jejunum was transected proximally 10 inches distal to the ligament of Treitz. The ileum was then transected 25 inches proximal to the ileocecal valve. The proximal ileum was anastomized to the transverse colon to drain the bowel taken out of continuity. Upon completion of this part of the operation an anastomosis was then performed between the proximal 10 inches of jejunum and the distal 25 inches of terminal ileum. The patient thus had 35 inches of small bowel in continuity and approximately 11 feet of small bowel out of intestinal continuity. She had an uneventful postoperative course. By December 7, 1964, her weight had decreased from 386 lbs. to 347 lbs. She was placed on a regular diet and discharged from the hospital on December 7, 1964.

The patient was readmitted to the hospital on 12-24-64 because of a wound infection. Her weight at this time was 334½ lbs. and she had been feeling well. For the first 10 days post operation she had about 12 very loose watery bowel movements each day, which now had decreased to three formed stools in the morning and three loose stools in the evening.

TURNER'S SYNDROME*

In this syndrome, there are several congenital anomalies consisting of iliac horns, dystrophy of the nails, anomaly of the patellae, chondrodysplasia and arthrodysplasia of the elbows. This condition is transmitted as a dominant hereditary character.

Most of the anomalies are essentially asymptomatic. The iliac horns are usually found in routine roentgenograms, but the finding of these suggests the presence of other abnormalities, namely the underdevelopment of the nails of the thumb and the index finger, with less constant anomalies such as a defect of the radial head, prominence of the acromion and clavicle, underdevelopment of the scapula and discoloration of the iris. In this syndrome there is a chromosome anomaly of the sex chromosome.

Abstracts, Briefs and Commentaries

DUMPING AND MALNUTRITION

This author is concerned with dumping, and has made certain studies and observations which appear to offer significant contributions to this almost overworked problem. He points out that the severe dumper is, in fact, relatively rare; but when the problem does exist to a severe degree, it is very serious. He applied his procedure to only eight patients over a period of eight years. They had not responded to any other procedure and had had weight loss on an average of about one third of their body weight before undergoing his procedure.

In order to eliminate the emotional and psychogenic factors and ascertain a true physiologic origin of the problem of the patient suspected of dumping, the investigators have induced the symptoms with 50% glucose into the pouch, but have mainly placed reliance on the absence of dumping symptoms when the patient was given 500 cc. of 5% glucose in normal salt solution in the course of one-half hour preceding a regular meal and an additional 500 cc. during the meal.

The corrective procedure involved the construction of a short reverse or antiperistaltic segment of jejunum. Following this procedure cineradiographic studies revealed that pouch-emptying following the corrective operation occurred more by dilution of contents by saliva, succus entericus and refluxed fluids from the duodenum, and piecemeal passage through the reversed segment, rather than by the usual peristaltic action, thus sufficiently slowing the pouch-emptying to prevent the postgastrectomy dumping syndrome.

Several studies and attempts at changes in the outlet or substitution of a portion of the pouch by other bowel have been performed, but in general have essentially failed. The major difference is the reversal of polarity or use of an antiperistaltic segment of bowel in Dr. Poth's procedure.

TREATMENT OF DECUBITUS ULCERS

When absorbable gelatin sponge (Gelfoam) was used in addition to the usual treatment for decubitus ulcers in 24 patients, fine, healthy granulations appeared quickly, and the wounds healed in an average of 30 days. Such rapid healing has not been obtained with the usual treatment, which includes: treating the patients on turning frames, maintenance of good nutrition, between-meal feedings, and the administration of antibiotics to which the cultured organisms are sensitive.

All wounds were free of necrotic tissue when treatment was initiated; this was accomplished by debridement when necessary. Culture and sensitivity studies revealed that most wounds contained resistant Staphyococcus aureus, along with the usual fecal organisms. Secretions, which varied from excessive to moderate and were purulent, became clear and diminished sharply in volume within several days after initiation of treatment. Laboratory studies of the secretions have not, as yet, been helpful in establishing a possible reason for the effectiveness of treatment.

The absorbable gelatin sponge (20 mm. x 60 mm. x 7 mm.), which is compressed in its sterile wrapper, was removed with sterile forceps and inserted into the deepest or most undermined portion of the wound once a day. No other treatment, e.g., skin cleansing or irrigation with solutions, was used. Dressings were not needed in most cases, but they were used if the material might fall out.

The clinical trials were undertaken after dramatic results were obtained when absorbable gelatin sponge was placed in a large ulcer of a paraplegic dog; the wound was healed in 1 week.

GALACTORRHEA

Seventy-one cases of non-puerperal galactorrhea are reviewed. Galactorrhea was categorized as either primary or secondary. Patients with primary galactorrhea, or the Argonz-del Castillo syndrome, were those who produced a milk-like secretion which was not connected with pregnancy. The secondary group was comprised of those patients who had been pregnant and who exhibited the Chiari-Frommel syndrome, characterized by post-puerperal galactorrhea, amenorrhea, and ovarian uterine atrophy. Eight of the 17 patients in this group had evidence of tumor. Two of the women in the group without evidence of tumor became pregnant during the period of observation, the galactorrhea persisting during pregnancy. Evidence of a pituitary adenoma was found in three patients with the Argonz-del Castillo syndrome. Three women with acromegaly and one with a craniopharyngioma also had galactorrhea. In 42 patients various endocrine deviations, mainly menstrual disturbances, but also thyroid disease, obesity and hirsutism, were accompanying disorders. Imbalance in the function of endocrine glands is pointed out as a possible cause for the appearance of galactorrhea in most of the patients.

COLLAGEN SPONGE FOR DIFFICULT OOZING

Peacock, Seigler and Biggers used tanned collagen sponge bovine tendon by the Eskon Laboratory in experiments on liver to control the surface oozing which would be evident after liver rupture. The collagen sponge graft could be a valuable technical adjuvant in the care of wounds of cellular organs or large surfaces where capillary hemorrhage is extensive and temporary fibrous tissue support is needed.

They found no antigenicity in the collagen sponge and no unfavorable reaction.

The fact that collagen sponge provides a temporary fibrous template for a new connective tissue synthesis and is completely absorbed in eight weeks indicates that it does have a value for the purpose for which it was intended.

The experimenters considered it to be contraindicated as a substitute for dura mater and to be of no value in reinforcing or adding tensile strength to wound deficits, such as large hernias. Likewise, it should not be used to restore or develop contour in cosmetic surgery.

It is suggested that in large areas of minor oozing, such as in places where gauze sponge is temporarily applied and removed at a later date, the tanned collagen sponge placed between the tissue and the gauze sponge serves to diminish the recurring oozing after the gauze sponge is removed.

There are instances in which continuous oozing is an annoying post-surgical complication. The tanned collagen sponge would seem to provide some value in these cases.

CONTUSION OF THE HEART

Demuth and Zinsser indicate that contusion of the heart occurs more often than is usually recognized. They add seven cases to the literature.

The history is relied upon for a definite injury usually to the chest or precordium and they suggest that though most authorities have stated that the large majority of patients recover uneventfully, their experience is that death may develop, unrecognized as having been caused by the injury. Of their seven patients, three died within the first twenty-four hours, three died between the first and the sixteenth day and one survived.

They indicate that the pathology is then similar to that which is observed from infarcts.

If the patient survives the first week after injury, complete recovery usually occurs, though late incapacity may result.

Treatment is similar to that which is given for coronary disease, except that if a definite diagnosis of contusion is made, it is probably inadvisable to use anticoagulants in a bruised heart because of the danger of extending the hemorrhagic process.

They note that with the increased incidence of car accidents, it would be well if cardiac evaluation be made immediately after the accident in order to allay unfair claims of heart damage at a later date.

MEASLES VACCINATION

The inadvertent introduction of measles into a children's hospital ward occurs frequently and offers a special threat to the tuberculous child. The measles vaccine was used as a prophylaxis after measles contact within a closed population of children under therapy for tuberculosis. The expected outbreak of regular measles was aborted. Signs and symptoms observed were similar to those in normal children who have been given the vaccine. The vaccinated children were protected from reinfection when regular measles was reintroduced into the ward.

THE FAMILIAR FACE

This paper presents an attempt, on the part of the hospital physician, to cope with the "Thick File Case." This clinical picture shows a high frequency in middle-aged women, with many years of regular attendance on the same family doctor, a full social and domestic life, multiple references and investigation without disclosure of significant organic disease, and failure in many cases to respond to symptomatic therapy or psychiatric treatment. The proposed management of such cases is that of detachment from the family doctor, attachment to a follow-up clinic at hospital, and guidance from one physician, also an attempt to uncover to the patients the emotional situations, and to explain the harm and damage being done to themselves and their family by this constant pursuit of ill health. Complete return to normal health is possible at any stage, providing the patient accepts and acts upon strong advice on re-orientation.

CARCINOMA OF CERVICAL STUMP

Of a series of 163 carcinomas of the cervical stump, 81 were classified as carcinomas of the true cervical stump, because the symptoms leading to the diagnosis developed 3 years or more after subtotal hysterectomy for a benign condition. Cases in which symptoms appeared before completion of the third postoperative year were designated as "coincidental." The cases of carcinoma of the true cervical stump in this series represented 4.5% of the total number of cervical carcinomas seen during the same period (1910-1960). The rapid increase in frequency of coincidental carcinoma of the cervical stump in the authors' material leads them to predict that carcinoma of the true cervical stump will also disappear within the next 20 years. In the coincidental series it was found possible to predict the occurrence of persistent cancer from the abnormal findings on the intravenous pyelogram. In the authors' experience, integral roentgen therapy has yielded very satisfactory results and constitutes the method of election for the treatment of carcinomas of the cervical stump.

TREATMENT OF PILONIDAL SINUS

At a U.S. Naval station hospital, comparison was made of hospital and outpatient surgical treatment of pilonidal abscess and sinus. This author found it entirely satisfactory to treat pilonidal abscess and sinus by local excision in the outpatient, packing the wound with gauze and then keeping the area cleansed and shaved, with dressings applied thereafter as indicated. He considered that the lesions healed in an average of 37 days and did not entail more than one day's disability from military service; and since the hospital-treated cases spent an average of 25 days in the hospital, he maintained that the outpatient treatment was just as effective as extended hospital care.

He speculated on the etiology of the disease, suggesting that the lesion develops as an infection around an ingrowing hair in the gluteal cleft, rather than as a congenital condition.

A bit more study in the etiology of this condition might have provided the author with considerable more enlightenment. In civilian practice it would be extremely rare to find a doctor who would confine his patient to the hospital for more than a day or two. However, as expense is apparently no criteria in a Naval hospital military regulations may require different procedures.

DIABETES AND TUBERCULOSIS

Patients with diabetes mellitus are more susceptible to tuberculosis and have more extensive disease. A review of 29 resections including 9 pneumonectomies and 6 segmentectomies, 2 decortications, and 3 primary thoracoplasties in 32 patients, indicated only a slightly increased morbidity and mortality rate over nondiabetic patients. Obesity is a common problem, especially in the Negro woman, making surgery and postoperative care more difficult. Management of the diabetes itself in the surgical period presented no specific complications. The diabetes was ameliorated postoperatively in 13 of the surviving 30 patients. Whereas four patients had preoperative spread of their disease, only one patient has had reactivation during the postoperative period up to 10 years, indicating the excellent postsurgical prognosis.

PORPHYRIA AND ANESTHESIA

In a patient with porphyria, even the most skilfully administered anesthetic may have a fatal outcome if it includes a barbiturate. No barbiturate should ever be given to a patient suspected of having porphyria. It is difficult to recognize this disease because it can simulate many other abdominal emergencies. When confronted with these emergencies, only an awareness of the disease and a knowledge of its intricacies will suggest the possible presence of this condition and lead to the testing of

Continued

urine for porphobilinogen. Porphyria represents a basic metabolic disturbance and appears in many forms. Two of these (intermittent porphyria and porphyria cutanea tarda hereditaria) both acute, are of importance to the anesthesiologist. The chelating agents have been used in the management of acute episodes with apparently good results, and this seems to be one of the most promising approaches for further study. The agents capable of precipitating an acute attack should be avoided such as the barbiturates, sulpha drugs, alcohol, heavy metals and oil-based paints, chloroquine, and progesterone. The over-all prognosis is poor. During an acute episode, the mortality rate in some series is as high as 50%. The future treatment of the disease may hold a large role for the anesthesiologist. Severe neurological involvement with respiratory failure may soon be treated in the respiratory unit and then, perhaps, the mortality rate can be lowered.

PTERYGIUM

A systematic sample of 463 veterans who had been operated upon for pterygium was compared to a similar sample of 19,000 veterans who sought medical and surgical care for any reason at Veterans Administration Hospitals. The relative frequency of veterans operated upon for pterygium increases as the latitude of the veterans' residence decreased. Rural veterans had a greater frequency of operation than urban veterans. Furmore, there was a significant association between U.S. Weather Bureau estimates of the ultraviolet radiation in sunlight in different parts of the United States, and the frequency with which rural veterans in these areas had pterygium operations. Ultraviolet radiation is proposed as an important environmental factor in the development of pterygium.

Medicine

Medicine is both a science and an art . . . It is an art when it becomes necessary to apply it to a human being who is ill, and this is especially true when the manner of treatment is under consideration. It is in this art that the physician reveals how much talent he possesses; he reveals himself as a true artist by the particular form of remedial preparation which he decides to administer to his patient, by the felicitous choice which he makes between remedies, and by the favorable manner in which he combines them. — Armand Trousseau (1801-1867)

Natura sanat, medicus curat morbos; ne noceas, si prodesse credis. (Nature cures disease, the physician merely does what he can to facilitate the operations of nature; in your efforts to afford relief be careful not to do permanent harm.) — Christoph Hufeland (1762-1836)

MODERN NUTRITION IN HEALTH AND DISEASE, 3rd Edition — M. G. Wohl, M.D. and R. S. Goodhart, M.D. Lea and Febiger, Philadelphia, 1964. 1282 pages.

This book, written by 62 authorities in the field including physicians and basic scientists, presents a very broad and comprehensive discussion of nutrition and diet in health and disease. This 3rd edition has been completely revised and rewritten and includes some additional chapters on inborn errors of metabolism, nutrition in alcoholism and nutrition in neoplastic diseases. Part I of the book, which has 17 chapters, is devoted primarily to the basic physiology and biochemistry of nutrition. Part II is devoted to the clinical aspects of nutrition in disease, including an excellent chapter on the treatment of diabetes mellitus. Part III discusses nutrition in pregnancy, infancy and adolescence, in the aging person and during stress. Each chapter contains a number of tables and is followed by a very comprehensive bibliography. Although much of the book contains material on the physiologic aspects of nutrition, the entire text is oriented toward clinical medicine, and is easy to read and to use as a reference.

This text should be useful and of interest to internists, general practitioners, surgeons and pediatricians and will be a very valuable addition to the clinician's library.

A DOCTOR DISCUSSES PREGNANCY — William G. Birch, M.D. with Dona Z. Meilach, Ph.D. Budlong Press Company, 1963. 110 pages.

This book is written in a very easy and understandable style and covers all aspects of prenatal care. It stresses particularly the relationship of the patient and her obstetrician. The responsibility of the husband and his understanding of the pregnancy is well outlined. This book is recommended for use in every physician's office who practices obstetrics. It will save him valuable time because so many common prenatal questions are so well answered. I have begun to use it in my practice.

N. M. Mensheha, M.D.

SURGERY OF THE BREAST — Jorstad, Louis H., C. V. Mosby Co., St. Louis, 1964. Price $15, 220 pages.

This beautifully illustrated and well-bound journal, dealing exclusively with breast surgery, provides only a meager manuscript in its various chapters.

The first 12 chapters provide no eye-appealing headings or subheadings to induce the reader's attention and compel his interest. Very excellent line drawings probably need no more caption than is provided.

What the book lacks in organization it makes up for in illustrations, excellent binding, and high-grade printing.

For the surgeon interested in tumors of the breast, the monograph should be one of his possessions.

Carl O. Rice, M.D.
Minneapolis, Minnesota

DRUGS OF CHOICE 1964-65 — Walter Modell, M.D., Editor. The C. V. Mosby Company, St. Louis, 1018 pages, $16.75.

This is the fourth biennial edition of a book designed by its editor, a well-known Cornell pharmacologist, as a "practical guide to the selection of the best drug for a particular therapeutic problem." Each chapter is devoted to a particular therapeutic grouping, ranging from Drugs For Diseases of the Heart, through Drugs For Cancer and Allied Diseases, to Drugs For Children and "Anorexients." The difficulties of such a classification are obvious. That the attempt is brought off successfully is a tribute to the editorial skill of Dr. Modell and the composing ability of the forty-seven contributors, among whom are listed such familiar names as Bonica, Barach, Dameshek, Lasagna, Moyer and Karnofsky.

Each chapter is designed to be an expression of the opinion of the author, or authors, as to the relative merit of the drugs in current use in his, or their, field. There is too much "listing" of drugs.

Some of the discussion is excellent, concise, and useful, however, and the text is recommended for occasional reference or browsing.

Rarity of Snakebites in Minnesota*

HENRY M. PARRISH, M.D., DR.P.H.**
Columbia, Missouri

MINNESOTA HAS the lowest U. S. incidence of poisonous snakebites west of the Mississippi River. Moreover, it has the fifth lowest snakebite rate for all states in this country (excluding Alaska and Hawaii). Those states with lower snakebite rates than Minnesota are all found in the New England Region. In keeping with this finding, there were no snakebite deaths in Minnesota during the 10-year period, 1950 through 1959.[1]

The purposes of this study are: (1) to chart the geographical distribution of poisonous snakebites in Minnesota; (2) to determine the annual incidence of snakebites; (3) to describe some medical and epidemiological characteristics of the bite accidents; and (4) to comment briefly on current concepts of snakebite treatment.

Poisonous Snakes

According to Klauber,[2] the following two species of poisonous snakes are indigenous to Minnesota: the timber rattlesnake (*Crotalus horridus horridus*) and the eastern massasauga (*Sistrurus catenatus catenatus*): a small rattlesnake. Both of these species are confined to the extreme southeastern part of Minnesota. Cottonmouth moccasins, copperheads, and coral snakes are not native to Minnesota. See Figure 1 for photographs of Minnesota's poisonous snakes.

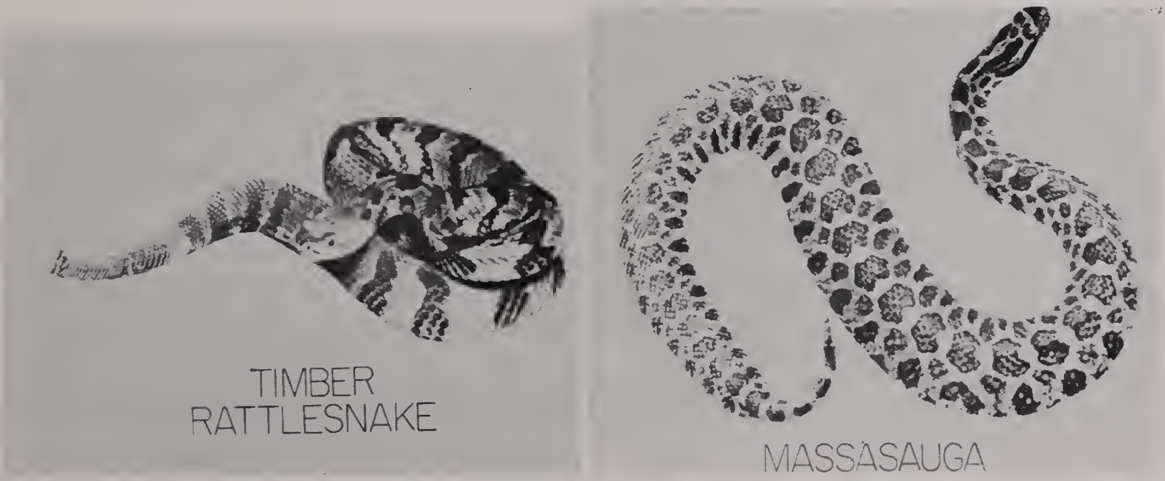

Fig. 1—Poisonous snakes indigenous to Minnesota. (Photograph of Massasauga Courtesy of L. M. Klauber, reference No. 2).

---

*This investigation was supported in part by Public Health Service Research Grant GM 11268-02 from the Division of General Medical Sciences, Public Health Service.

**From the Department of Community Health and Medical Practice, School of Medicine, University of Missouri, Columbia, Missouri.

Continued

All of Minnesota's poisonous snakes are pit vipers, so named because of a characteristic pit which is located between the eye and nostril on each side of the body. Pit vipers are also identified by elliptical pupils and two well-developed fangs which protrude from the maxillae when the snake's mouth is opened. Rattlesnakes have rattles attached to their tails. Harmless snakes do not have facial pits; they have round rather than elliptical pupils, and while they have teeth, they lack fangs.

Frequently people chop off the head of a snake which has bitten someone and bring the snake's body in for identification. Pit vipers can be identified by turning the snake's belly upwards and noting a single row of subcaudal plates just below the anal plate. Harmless snakes have a double row of subcaudal plates. Figure 2 depicts the characteristic features of pit vipers and harmless snakes.

Methods of Study

A questionnaire and letter explaining the purpose of this study were mailed to a "selected" group of Minnesota hospitals listed in Hospitals (Journal of the American Hospital Association) Guide Issue. Those selected for this study were general hospitals, children's hospitals, and college infirmaries. Army, Navy, Coast Guard, Public Health Service, Air Force and Veterans Administration hospitals also received questionnaires. Maternity, tuberculosis, and mental hospitals were omitted, as they would not be expected to treat snakebite victims. A total of 169 Minnesota hospitals comprised the study group. Each hospital was requested to report all inpatients admitted for snakebite treatment during 1958 and 1959.

Most hospitals do not code and tabulate the diagnosis of emergency room and outpatient clinic visits. Since some snakebite victims are not admitted to the hospital as inpatients, it seemed essential to ask a sample of practicing physicians how many snakebite victims they treated on both an outpatient and an inpatient basis. Previous surveys[3,4] have shown that most people with venomous snakebites are treated by general practitioners, surgeons, internists, pediatricians, or orthopedic surgeons. Therefore a random sample of one third of all the Minnesota physicians listed in these categories of practice in the A.M.A. American Medical Directory were sent questionnaires.

Death certificates for fatal snakebite cases were requested from the Minnesota Department of Health.

Results

This report is based on questionnaires returned by 169 Minnesota hospitals and is supplemented by questionnaires returned by 582 (81 per cent) of 715 practicing physicians in the State. The Minnesota Department of Health indicated that there were no snakebite deaths during 1958 and 1959.

Incidence

Minnesota hospitals reported a total of four inpatients treated for poisonous snakebites during 1958 and 1959, and *all of the analyses in this paper, excluding the estimate of incidence, were based on these four detailed case reports.*

On the basis of physicians' reports, when adjusted to account for all Minnesota physicians in the practice categories mentioned, it is estimated that approximately three people are treated annually for poisonous snakebites in Minnesota. This provides an incidence of 0.09 bites per 100,000 population per year.

Geopathology

The geographical distribution may be seen in Figure 3, the lightly shaded counties being those from which hospitals reported inpatients treated for snakebites.

Of four persons hospitalized for snakebite treatment for whom detailed records were available, two were bitten by rattlesnakes, one by a foreign snake, and one by an unidentified poisonous snake, most likely a rattlesnake. This bite occurred in one of the southeastern counties but was treated in St. Paul. A pet-shop worker was bitten by a foreign snake, an African rhinoceros viper (*Bitis nasicornis*).

Figure 3 shows that all of the snakebites occurred in southeastern Minnesota, showing the geographical patterns of bites to be consistent with the ecological ranges of poisonous snakes in Minnesota, as described by Klauber.[2]

Temporal Relationships

Snakebites were infrequent during the colder months of the year—Au-

Continued

gust through April, since snakes are usually inactive or hibernating during the colder months. The foreign snakebite, however, occurred in February. Of the bites by native snakes, one occurred in May, one in June, and one in July. The seasonal distribution of bites by native snakes coincides with the season when snakes are most abundant and active and when people undergo greater exposure due to out-of-doors occupations and recreation. Similar "seasonal epidemics" of venomous snakebites have been observed in New England and North Carolina.[3,4]

The times of day when the snakebite accidents occurred were: 9:00-11:59 A.M., one bite; 12:00 noon-2:59 P.M., two bites; 3:00-5:59 P.M., no bites; and 6:00-8:59 P.M., one bite. There were no bites from 9:00 P.M. through 8:59 A.M.

Fig. 3—Geographical distribution of poisonous snakebites in Minnesota, 1958 and 1959.

Bite Victims

There were three white males and one white female. Males usually have higher snakebite rates than females, and whites have higher rates than nonwhites.

Age and Sex

An analysis of the ages and occupations of the victims showed that one was a child, aged 12, one a housewife, aged 25, one a farm laborer, aged 63, and one a pet-shop worker, aged 34.

Two were bitten while handling a poisonous snake, one while picking berries in a field away from the house, and one while walking through a field away from the house.

Site and Severity

Two bites were on the fingers; the other two were on the lower extremities.

A modification of the clinical classification of pit-viper venenation* by Wood, Hoback and Green[5] was used to determine the severity of bites. Bites were classified as follows:

Grade 0—*No venenation.* Fang or tooth marks, minimal pain, less than 1 inch of surrounding edema and erythema. No systemic involvement.

Grade I—*Minimal venenation.* Fang or tooth marks, severe pain, 1-5 inches of surrounding edema and erythema in first 12 hours after bite. No systemic involvement usually present.

Grade II—*Moderate venenation.* Fang or tooth marks, severe pain, 6-12 inches of surrounding edema and erythema in first 12 hours after bite. Systemic involvement may be present—nausea, vomiting, giddiness, shock or neurotoxic symptoms.

Grade III—*Severe venenation.* Fang or tooth marks, severe pain, more than 12 inches of surrounding edema and erythema in first 12 hours after bite. Systemic involvement usually present as in Grade II.

There were no fatalities from snakebites in Minnesota from 1950 through 1959.[1] The case-fatality rate for snakebites in Minnesota is estimated to be less than one half of one per cent.

Treatment

A constricting band should be applied lightly to the involved extremity several inches proximal to the bite and only tight enough to occlude the superficial venous and lymphatic flow. *It should not occlude the arterial circulation* and it should be released every 10 to 15 minutes for a minute or two. As edema resulting from venom poisoning spreads, the constricting band should be advanced to keep just ahead of the swelling.

Incision-and-suction is effective in removing venom from experimental animals up to about 120 minutes after the venom is injected. The sooner it is used, the larger the amount of venom that can be removed. Suction should be used for about one hour. We have found the suction cups supplied in the Cutter and the Becton-Dickinson snakebite first-aid kits effective. Incisions, one-quarter inch long and one-eighth to one-quarter inch deep, are made into the subcutaneous tissues over the fang punctures. A few (3 to 5) additional incisions may be made in the surrounding edematous tissues, but a large number of incisions is not necessary. Immobilization aids in limiting the spread of venom; however, if one must decide between immobilization or seeking prompt medical treatment, the latter should be sought.

The "3 A's" (antivenin, antibiotics, and tetanus antitoxin and/or toxoid) are recommended, in addition to incision-and-suction, in treating all serious pit-viper bites. Antivenin Crotalidae Polyvalent (Wyeth) is effective in neutralizing the venoms of all North American pit vipers, but it is not protective against coral-snake venom. Since antivenin is manufactured from horse serum, the patient should receive a skin test before antivenin is given. For Grade I venenations antivenin may be adminis-

---

*See Test Your Word Score Page 1029.

Continued

tered in the deltoid or gluteus muscles. In Grade II and Grade III venenations, antivenin diluted in 1000 cc. of normal saline may be given intravenously.[6] Studies with radioisotopes have shown that antivenin accumulates at the site of the bite more rapidly after intravenous administration than after intramuscular administration.[7] Injection of antivenin into the local bite area is not a particularly effective way to administer antivenin.

The following amounts of antivenin have been found useful in treating the various grades of venenation: Grade 0 requires no antivenin; Grade I may require 10 cc.; Grade II requires 30-40 cc.; and Grade III requires 50 cc. or more.

Since snakes' mouths and venoms may harbor pathogenic organisms, antibiotics and tetanus antitoxin and/or toxoid should be given prophylactically. Gram-negative organisms predominate; hence a broad spectrum antibiotic is indicated. Penicillin used by itself is not adequate treatment.

Antihistamines are contraindicated, as they shorten the survival time of animals poisoned with pit-viper venoms. Shock resulting from venom poisoning should be treated with infusions of blood, plasma, saline solution and vasopressor drugs. Meperidine hydrochloride and other analgesics may be given to relieve pain. Recently there have been reports of excessive tissue necrosis and amputations associated with cold therapy, such as packing an extremity in ice or using ethyl chloride.[8] In my opinion, cold therapy should not be used in treating pit-viper bites.

Summary

Poisonous snakebites rarely occur in Minnesota. An estimated three people are bitten annually, which provides an incidence of 0.09 bites per 100,000 people. The case-fatality rate is estimated to be less than one half of one per cent.

Most of the reported bites occurred in southeastern Minnesota from May to August. Of four bites reported in detail, two were inflicted by rattlesnakes, one by a foreign snake, and one by an unidentified snake. All of the bites were on the extremities.

The treatment recommended included incision and suction and the administration of antivenin, antibiotics and antitetanus prophylaxis.

Perinatal Mortality Study

Fetal Death During Labor*

Case Report

The mother of this infant was 27 years old and Rh positive; she had had no difficulty with the present third pregnancy or with her other two pregnancies. Both of her children are living and well.

At 38 weeks of gestation she spontaneously went into labor and entered the hospital after six hours of labor. At this time her blood pressure was 120/80, fetal heart rate 140 per minute and fetal station minus 2. Although the mother continued to have mild contractions, she had no further examinations or check of fetal heart rate until six hours after admission (12 hours after onset of labor), at which time the uterus was very tense, the cervix 2 cm. dilated and fetal station minus 1, and the fetal heart tones absent. The mother's physician was called; he did a sterile vaginal examination 45 minutes later and made the diagnosis of possible abruptio placenta. The membranes ruptured one hour later (blood pressure recorded second time since admission — 120/80).

A stillborn infant weighing seven pounds, four ounces was born 12 hours after admission. No autopsy was done. The placenta, which immediately followed the infant, was covered with numerous blood clots. Following delivery, the mother's hemoglobin was 8.9 gm.%. (The hemoglobin had not been checked before delivery; it was 74 to 80 per cent during pregnancy.) The mother's fibrinogen level following delivery was 75 to 125, which was considered borderline. She received one pint of blood, which raised the hemoglobin to 10.1 gm.%.

Comment

The Ramsey County Perinatal Mortality Study Committee criticized the care which this mother received while in labor. As long as the mother continued to have mild contractions, there should have been a check of her blood pressure and fetal heart rate at least once each hour. Blood pressure, rectal examinations of the cervix and fetal heart-rate determinations should be done and recorded at least every 30 minutes during active labor in multiparous patients. Hemoglobin should be done on admission.

Although more frequent listening and recording of the fetal heart rate may not have made a difference in the final outcome in the present case, possibly there might have been a marked drop in the fetal heart rate before it ceased altogether. With this drop, measures could have been carried out to deliver this full-sized infant before it expired. The Committee will continue to study perinatal deaths and attempt to find factors, the use of which may salvage some of these infants.

Industrial Medicine

The Medical Evaluation of Physical Disability in the Employee

S. CHARLES FRANCO, M.D.*
New York, N. Y.

IN INDUSTRY the evaluation of disability is important in a variety of conditions involving extended sick absence, physical impairment, and behavior problems. It consists of rating the physical or mental impairment so that an appraisal of the employee's ability to engage in gainful and productive work can be determined.

At Consolidated Edison, the function of the medical department in the disability evaluation program is to obtain specific diagnostic information that will be useful in guiding management in reaching a proper administrative decision. The confidentiality of medical records must also be maintained.

Disability Panel

The disability panel is composed of representatives from the personnel department (the personnel director acts as chairman) and the medical department, a supervisor from the employee's department and a representative from the executive level of management. If the employee's disability is the result of occupational injury or disease, a member of a company's insurance bureau also attends the meeting.

The panel procedure consists of a weekly meeting to consider the cases presented to it by the departments. Its evaluations and recommendations as to disposition of cases are based on factors such as the medical report, the worker's service record, his attendance and job performance records, and his status with regard to disability under the union agreement.

The report covers the employee's attitude, job performance, and absence record. The whole problem is then discussed by the panel; but the primary responsibility for decision rests with the department concerned. In the event of a failure to reach a

---

*Executive Director of the Medical Department, Consolidated Edison Company of New York, Inc.

Continued

decision the problem is then reviewed by the vice president of the department concerned.

It was revealed that the majority of cases reviewed at Consolidated Edison were over 45 years of age with more than 25 years of service. The 10 most common disabling diseases were:

	No. Employees	%
Cardiovascular disease (coronary disease-171)	230	(32.6)
Functional nervous disorders (psychoses-60)	140	(19.8)
Cancer	55	(7.8)
Fracture	37	(5.2)
Arthritis	26	(3.6)
Peptic ulcer	20	(2.8)
Herniated intervertebral disc	15	(2.1)
Cerebral vascular disease	13	(1.8)
Chronic bronchitis and emphysema	13	(1.8)
Cirrhosis of liver	12	(1.7)

Multiple Disease

As is common in an older age group, a fair percentage were affected by more than one disease. Further scrutiny of the cardiovascular disease system indicates that coronary artery disease accounts for 75% of the disabling conditions. The complications of hypertension account for most of the hypertensive vascular disease. The relative infrequency of rheumatic heart disease is also reflected in the statistics.

Functional Disorders

Functional disease of the central nervous system is the second most prevalent condition. The psychoses were usually identified by a medical report of sick absence from a physician. At times abnormal behavior on the job provided the first signs to supervisors, and a medical referral to the diagnostic clinic was obtained on an emergency basis. As would be expected in an older age group, affective psychosis accounted for 75% of the cases. A change in personality, increased sick absence, and deteriorating job performance were often clues in the neuroses. The anxiety neuroses were frequently associated with medical complaints. Outside neuropsychiatric consultation is obtained in all cases for guidance and recommendation.

Fifty Percent Re-Employable

A review of the functional nervous disorders (Table 4) indicates that approximately 50% of the employees were returned to duty. The over-all attendance record, previous occurrences of psychiatric disorders, and the department's evaluation of work performance were important factors in the consideration for approval to return to work. Retirement was most often recommended in cases with recurrent episodes, excessive sick absence, and deteriorating work performance. By and large the subsequent work experience of the recovered neuropsychiatric case has been satisfactory. Physically restricted duty was required in a little more than one third of the cases, usually with reference to the responsibility for safety of others in certain hazardous job operations. At times, some recovered psychotics were restricted to job activity under close supervision.

Alcoholism

A majority of the alcohol problems (75%) were reviewed. Some had availed themselves of therapy, but nearly 25% were identified by medical examination as revealing the chronic sequelae of organic disease, such as cirrhosis, polyneuritis beriberi and malnutrition.

Retirement Recommended

Retirement was recommended in 85% of the cases of alcoholism reviewed by the panel. Many employees were considered for recurrence of drinking episodes under the procedure on alcoholism; a number of these had not followed any type of medical therapy. Others had not been identified under the company procedure on alcoholism, and their recognition at an advanced stage of the disease made any attempt at rehabilitation unrewarding. By contrast, the long-term experience under the procedure on alcoholism with employees who had followed the recommended treatment has shown a 60-percent rehabilitation rate.

Cardiovascular Disease

A more detailed analysis of the cardiovascular disease cases is rendered in Table 1. Of those who survived the acute attack of coronary thrombosis, 56% returned to productive work.

Sick Absence

Sick absence constitutes a major problem. Any sick absence extending beyond five days requires examination in the medical department before return to duty can be approved.

The medical reports of all cases of sick absence extending beyond two weeks are promptly reviewed by the medical department to establish the cause of illness. Periodic re-evaluation of follow-up reports is scheduled at intervals based on the nature of the underlying disease. In addition to the usual channels of communication with the attending physician, evaluation based on physical examination in the medical department or at home may be required. Hospital cases are usually deferred until the convalescent period has been completed. Under company procedure sick absence extending beyond eight weeks requires review by the disability panel.

Medical administrative opinion should be based on good clinical practice rather than on "book rule." The industrial physician has a moral obligation to consider the employee's rights to his job as well as his physical welfare.

Cardiovascular Disease

Limited Activity

Most of the cases of cardiovascular disease will require limitation on heavy lifting and repeated stair climbing and, in severe cardiacs, walking or continuous standing may have to be curtailed.

Angina Pectoris

Employees with angina pectoris or convalescent from acute coronary thrombosis should not be assigned to jobs in which the sudden occurrence of symptoms would endanger the safety of others. They should not drive motor vehicles.

Asymptomatic Coronary Disease

The asymptomatic employee with coronary thrombosis can return to physically restricted work three to four months after his acute episode. The asymptomatic patient with a stable electrocardiogram may be permitted to drive light vehicles at the end of one year after an acute episode. There are some who have recommended that the asymptomatic coronary thrombosis case can return to "his former work" even at a rela-

TABLE I

†Over-age cases (65-68 years).

Continued

tively heavy job. We are impressed by the adverse effect on industrial relations when the "recovered coronary" has a recurrence or dies on the job. We also have seen the untoward effect of heavy physical work on the recent coronary thrombosis patient. In the past 15 years, recurrences on the job have been practically nonexistent in our physically restricted coronary disease group. There has been only one claim made under compensation since 1950 and this was rejected by the Workmen's Compensation Board.

The coronary artery disease patient who has made a complete clinical recovery may be considered for full duty after a two-year follow-up. The asymptomatic individual with normal blood pressure, and normal cardiac size, without diabetes, and with a normal, double 2-step exercise electrocardiogram test can be considered for return to full duty without physical restrictions. Unfortunately this number is relatively small and comprises less than 5% of the cases of coronary thrombosis.

Hypertension

Cases of essential hypertension, with blood pressure levels up to 180/100, usually will not require physical restrictions. However, every clinical precaution should be taken to uncover latent coronary disease.

Persons with rheumatic heart disease, who have not experienced congestive failure, can perform surprising amounts of physical exertion without obvious detrimental effects. Aortic valvular disease usually poses more problems than mitral involvement.

Arthritis, Back Disorders, and Discogenic Disease

Avoidance of work assignment in wet or damp locations or in sustained low temperatures is important in the medical management of the arthritic employee.

Osteoarthritic joints with definite degenerative changes should be spared further trauma as well as additional wear and tear. However, one should avoid the pitfall of hypertrophic spurs on the bodies of spinal vertebrae without other distinction.

Depending on the location of the arthritic condition, work in certain cramped positions should be avoided.

An employee with a functional type of back complaint may make a rather remarkable improvement when his job is placed in jeopardy. It would be wise for the physician to document carefully the employee's reaction to various work assignment when there is an absence of limiting clinical findings to confirm an organic back complaint.

It has been our experience that preemployment x-ray films of the spine often do not identify potential back conditions. Herniated disc is the most common back condition, and the vast majority of patients with it show normal x-ray films.

A well-motivated employee, after operation for herniated disc, can often resume heavy work despite the recognized anatomical alteration in the spine.

Pulmonary Disease

In cases of healed pulmonary tuberculosis, nonspecific pulmonary fibrosis, chronic bronchitis, emphysema, and asthma, patients require a protected work atmosphere as regards dust, dampness, changing temperature, and extremes of temperature.

It has been a common clinical experience that spontaneous pneumothorax rarely recurs after a six-month interval, and it is not practical to continue physical restrictions on heavy lifting beyond that time.

Neurological Disorders, Epilepsy, Syncope, and Vertigo

Cerebral thrombosis constitutes the largest proportion of this group. In the absence of hypertension, the cerebral thrombosis cases may be rehabilitated to a surprising level of work performance. Evaluation of permanent impairment should be deferred until maximum rehabilitation has been achieved, which may take up to six months. Nevertheless, employees who have had cerebral thrombosis will continue to require certain physical restrictions to protect them against unusual strain and working in hazardous situations. Recurrence of vascular episodes can be expected in a four-year period[5] in 50%.

Subarachnoid hemorrhage, on the other hand, imposes a continuing hazard even at protected jobs.

Convulsive Seizures

Persons with convulsive seizures require careful neurological survey, including at least an electroencephalogram to determine, if possible, the etiological factor. In some cases it may be wise to perform cerebral angiography and pneumoencephalograms. Syncopal episodes under severe functional stress should not be the cause for precipitous application of physical restrictions of a permanent nature. Obviously, the epileptic should work in a protected environment and should not be responsible for the safety of others. A hidden alcoholism problem may also manifest itself by convulsive seizures.

Vertigo

Functional vertigo raises many problems. Reassurance of the employee by a complete medical work-up can serve to eliminate a certain percentage of these cases from serious consideration.

Persons with multiple sclerosis and amyotrophic sclerosis involving disability of locomotion can be placed at sedentary work. However, involvement of the upper extremities may pose a serious disability. The progressive nature of these conditions requires careful periodic re-evaluation.

Neuropsychiatric Problems

Persons with anxiety neurosis, psychosomatic disturbances, and reactive depression may make a good response to treatment and are capable of productive work.

More persistent problems arise with psychoneurosis, recurrent depressive psychosis, and schizophrenia. Such individuals may not be able to carry the full responsibility in an operating job assignment in a public utility. They may require work under close supervision.

The suicide risk, even when recovered, needs close supervision at work for a varying period.

Borderline Personality

Persons with a borderline personality, functioning between normal and pathological, may present abnormal behavior on the job, poor work performance, and increased absenteeism, and may show very few clinical findings. The disposition of these problems is often administrative because the medical department may not be able to identify any legitimate underlying medical or psychiatric condition.

Diabetes Mellitus

The mild controlled diabetic, even one who takes small amounts of insulin (up to 10 units N.P.H.), may not require physical restrictions.

Driving Hazard

Where there is danger of insulin shock, the employee should be limited with respect to driving and hazardous work. In the matter of driving motor vehicles, the diabetic who requires insulin is excluded from truck driving, but those whose insulin dosage is moderate (up to 40 units of N.P.H.) may be able to drive passenger vehicles.

The "brittle" diabetic whose control is difficult should avoid shift work, particularly the "graveyard" shift from midnight to 8 A.M.

In the presence of organic complications, such as peripheral arterial disease, cardiac, or renal involvement, appropriate protective measures must be taken.

Abdominal Conditions

We use this category to cover a variety of gastrointestinal and genitourinary diseases.

Chronic peptic ulcer symptoms may be disabling enough to require elimination of shift work. The complications of peptic ulcer may be considered as an indication for surgical intervention.

The relationship of colon disorders to psychosomatic disturbances is well known.

Summary

The medical evaluation of physical disability is the key to the safe and productive employment of the physically impaired worker. It is the firm basis for selective placement at a suitable job. Follow-up by periodic medical evaluation is also an important factor in keeping the handicapped employee on the job without harm to himself.

**Happily,
not all your patients
are overweight**

**but
for those who are…**

Bamadex®

d-amphetamine sulfate (15 mg.) and meprobamate (300 mg.)

Sequels®

Sustained Release Capsules

Most overweight patients could benefit from the appetite control provided by the prolonged anorexigenic-tranquilizing action of BAMADEX SEQUELS: anorexigenic action through the central stimulant effect of the amphetamine; tranquilizing action with only mild sedation through meprobamate; prolonged action through sustained release of active ingredients.

Contraindications: Hyperexcitable and prepsychotic states; patients hypersensitive to meprobamate.

Side Effects: Occasional allergic skin reactions may occur with meprobamate, accompanied by fever, nonthrombocytopenic purpura, angioneurotic edema, hypotension, or bronchial spasm. Drowsiness with or without ataxia and/or alteration in visual accommodation may occur. Effects of alcoholic beverages may be increased by meprobamate. Use with caution in patients with coronary or cardiovascular disease or severe hypertension. Prolonged use may result in dependence. Reactions can occur if drug is not withdrawn gradually.

Medicine and Religion

The Physician and Reality Therapy

ELOF G. NELSON, S.T.M.*
Minneapolis, Minnesota

Reality is the concrete embodiment of truth. All dimensions of reality are germane to the physician's management of the whole person. To ignore the patient's spirit and the manifestations of that spirit in religio-social living is as incomprehensible as ignoring the patient's vascular system. We need to begin asking people: "What makes you tick?"

Everything about this space age in which we live has exciting possibilities for good as well as for evil. Our dynamic culture, filled with the fruits of the Industrial Revolution, scientific progress and its concomitant socio-economic bonanza, points to a negative as well as a positive outcome.

Our houses, offices, bank accounts and leisure activities reflect the many "assets" of space-age living. We have more things to make us happy than any generation in all human history; however, we are neither a happier nor a more grateful generation. The more man has, the more he seems to live on the edge of poverty with a thousand needs and wants.

We are all rather familiar with the facts — or symptoms, if you wish to think of them in clinical perspective. I shall not enumerate here the sociological and cultural trends of our time. Anyone who spends his daily life treating people has long since collected his own clinical evidence.

Success is a difficult reality factor to live with. American people apparently are not genotypically capable of living with it. Far too many are incapacitated by psychic pain resulting from the stresses of life, because they simply do not know how to adjust to a "successful culture." Many of your patients live in an existential vacuum; they are neither pilgrims nor tourists, but wanderers.

People are stunned by this turbulent culture. They feel the whirling pace around them filling them with anxiety, frustration, and conflict. Nothing makes sense, and they drift into many kinds of unrealistic thought, affect and activity. We note a deluge of symptoms: boredom, loneliness, spiritual malaise, purposelessness, psychosomatic illness and the many neuroses.

Sick Societies Produce Sick People

Reality has always impinged on human life with anguish and pain. As T. S. Elliot says, "We can't stand reality very long." We are becoming masters of self-deception and we find it increasingly convenient to project responsibility to other persons or things. Not many people can stand the truth about themselves and their obligation as mature persons of meeting life's crises and demands in a rapidly changing world. Vast numbers of people are escaping into illness and apathy.

American culture seems to be saying that the aim of life is to avoid facing up to reality and to attain happiness by any means desirable. We are on a massive "happiness kick"; we must not deny ourselves anything; what we want, we ought to have here and now. We have become a culture which has begun to scorn the old patriarchal values of decency, honesty, loyalty, honor, and integrity. People no longer know who they are, as one scene from "Death of a Salesman" vividly illustrates. The words were uttered by Willie's

Continued

---

*Director, Department of Religion & Health, Fairview Hospital.

own son at the graveside: "The trouble with Willie was that he never knew who he was." Depersonalized man is a strong candidate for physical, emotional or moral suffering. Perhaps, therefore, life's greatest tragedy is not that people die — but that some people never learn how to live.

Help People Test All of Reality

For many people, their psychic metabolism is out of gear and life meaningless. They are suffering from a "philosophical neurosis," all too evident in such physical findings as fatigue, and psychosomatic aches and pains, as well as in all types of addictions and escapes from reality.

Religion too has become a dull habit, something to exploit rather than to live. In American life today, there is great religious exposure but little religious commitment; people are submitting to the values of faith but there appears to be little surrender. If we take a moment of time to analyze people, we discover that they have a distorted world view and exist in a vacuum of philosophical poverty. They are spiritually bankrupt.

Individuals expect their God to be a great White Father, something like Santa, who doles out jobs and promotions, assures optimum working conditions for all, and provides bulging bellies, fast cars, and plenty of playthings for week-end pleasure.

The seven deadly sins of pride, envy, anger, sloth, avarice, gluttony and lust are spiritual cancers which daily take their toll in our patients' lives and may well be greater factors in the practice of medicine today than ever before in its history.

Patients often feel a relationship of trust toward their physicians; perhaps no one else but the physician can so relate to the patient. Pastors in larger metropolitan areas have neither the time nor the training to counsel; and often people in these communities are reluctant to relate to their pastor on a personal, subjective level.

Suggestions for Management

Physicians would do well to manage the whole person by thinking in terms of social-religious living as well as organic-physiological constructs. Helping people to face total reality, not excluding the spirit of a man: this I would call reality therapy. In this therapy the physician should involve himself in a teaching role; he should challenge, modify or correct behavior, thought, feelings and motives arising from the soul of man.

The following steps may give you new "pastoral tools" to aid in facilitating treatment of the whole person:

A. Ask:
  1. Are you content with yourself?
  2. Are you getting along with others reasonably well?
  3. Are you accepting responsibility for your mistakes and success in life?
  4. Are you living a good life — are you *sure* you know right from wrong?
  5. What are you living for — what is the central, controlling idea in your life?
  6. Is that central, controlling idea big enough to live well for — is it worthwhile dying for?

B. Emphasize the person's condition as weakness or indifference, *not* illness.

C. Point out that weakness can be strengthened by:
  1. Meeting life's responsibilities daily.
  2. Confronting, *not* evading life's conflicts and disappointments — thus developing moral and ethical consciousness.
  3. Understanding the nature of love: learning to give and receive love.
  4. Placing positive values on the focal points of reality about which we all feel ambivalence: Birth, Death, Love, Sin, Illness, Crisis.
  5. Living the seven virtues: Wisdom, Justice, Courage, Temperance, Faith, Hope, Love.

Man cannot live by bread alone. As you challenge, modify or change people's style of living by giving meaning, purpose and commitment to life, you will stand people on their feet.

There is nothing so well known as that we should not expect something for nothing — but we all do and call it Hope. — E. W. Howe

History of Medicine

Joseph Lister (1827-1912)

> *It was his part to learn of the power of Medicine and of the manner of healing and, heedless of glory, to exercise that quiet art.*
> —*Virgil, Aeneid xii, 396-7*

This year we celebrate the centenary of the first successful case treated antiseptically by Lister, who is inseparably linked with the history of antiseptic surgery.

The frightful mortality in the years before "Listerism" . . . "was the burden of all military surgery, all hospital and private practice, all midwifery, in every city on earth, for centuries. Pyaemia, septicaemia, erysipelas, cellulitis, hospital gangrene . . . we have only to note that these infections were scourging the Glasgow Infirmary, to their hearts' content, right up to 1865, as they were scourging other hospitals in all countries; and were called . . . hospital diseases."[1]

Joseph Lister was brought up in the tranquil, unpretentious atmosphere of a Quaker family. His father, Joseph Jackson Lister, a man of remarkable attainments, gave his leisure time to microscopic studies. To his investigations we owe the production of the achromatic lens and the perfection of the modern telescope. The Quaker abstention from more worldly amusements also provided the incentive to young Lister to pursue natural history studies and read the Latin classics. He announced when very young his intentions of becoming a surgeon. Studying at University College, London, Lister came under the influence of two exceptional professors, Wharton Jones and William Sharpey. From Jones, who had made important discoveries in physiology, Lister began to study the circulation and the effects in inflammation on the web of the frog's foot. During the years he spent as a Resident Doctor at University Hospital he joined with a brilliant group of young enthusiasts in the Hospital Medical Society, conducting research and reading original papers. Lister's papers on "Gangrene" and "Observation on the Muscular Tissue of the Skin" indicated the direction in which his mind was working.

Upon the advice of Professor Sharpey to visit Edinburgh to observe some of their methods, Lister went in 1853. Soon he was asked by Dr. James Syme, Professor of Clinical Surgery at Edinburgh University to be his assistant in his private practice as well as at the Royal Free Infirmary. Syme was one of the great surgeons of his day. Under his tutelage Lister matured as a surgeon and also carried out important research concerning inflammation and blood coagulation. Their compatible professional relationship was enhanced by the marriage of Lister to Agnes Syme, Doctor Syme's eldest daughter. At his post as Assistant Surgeoncy at the Infirmary, Lister continued his researches into the causes and exact nature of inflammation.

In 1860 he was appointed to be Professor of Surgery at the University of Glasgow and Surgeon at the Royal Infirmary. By 1865 he had done a vast amount of scientific work on the subject of inflammation. Seeking a solution to the problem of wound infections, Lister became interested in Pasteur's work. Now that the French chemist had shown that decom-

Continued

position was due not to the air but to the living organisms carried by particles of dust in the air, Lister decided to try to prevent infection by excluding the air from wounds with a dressing containing a material potent enough to destroy the floating particles. ". . . to apply some chemical substance in such a manner that not only would the microbes already present be destroyed, but the germ-killing substance must act as a barrier between the wound and all sources of outside infection."[2] He used as his first antiseptic agent full strength carbolic acid, which under the name of German creosote, was supplied to him by his colleague, Dr. Thomas Anderson.

His first successful case to test his new principles was that of an eleven-year-old boy admitted to the Glasgow Royal Infirmary on August 12, 1865, suffering from a compound fracture of the left leg caused by the wheel of a cart passing over the limb a little below the middle. "A piece of lint soaked in the undiluted carbolic acid was applied to the wound, after which the limb was padded and placed in the usual splints. The limb was left undisturbed for four days. . . . Lister found, to his joy, that there was no sign of suppuration in the wound."[3]

With profound care and watchfulness he progressed from case to case, modifying his first method as he found that a dilution of the acid was sufficient to effect asepsis in wounds. His carbolic acid spray, sometimes called the "Donkey machine" was with him at every operation for many years, altho it did produce irritating vapors.

He introduced the catgut ligature and was constantly experimenting and improving it. "Lister prophesied that it would be possible to tie arteries in their continuity in cases of aneurism, and that it would be no longer dangerous to ligature an artery close to the emergence of a large branch. Before applying these ideas to the human subject, he experimented upon an old horse on December 12, 1867. The horse made an excellent recovery. Indeed, its condition improved greatly under the good feeding and management of the veterinary establishment, but in five and a half weeks it died from old age. Lister, who made a post-mortem examination, found his expectations fulfilled. Not only had the artery been successfully occluded, but the ligature had been surrounded by strong fibrous tissue, and there were no signs of pus, granulations or softening of the tissues."[4]

"As the years passed by it became recognized, both by the profession and the public, that he was the greatest surgeon the century had produced, and honors, British and foreign, were showered thickly upon him. . . . Long before he died he had become a national hero, and an object of world-wide respect."[5]

The name of Joseph Lister will ever be honored and venerated as one of the greatest benefactors of the human race. The results of his manifold labors may be summed up in a phrase: he made surgery clean.

The University of Minnesota Department of Pediatrics continuation course in pediatrics, September 21-23, University of Minnesota Campus in Minneapolis. "Genesis, Epigenesis, Modern Physic and the Child" is the subject. Contact: Edward Defoe, Department of Pediatrics, University of Minnesota Hospitals, Minneapolis 55455.

* * *

Three day meeting in Cardiology at the Lowry Hotel, St. Paul, September 15-17, under the sponsorship of the Council on Clinical Cardiology of the American Heart Association, the St. Paul Medical Center, and the Minnesota Heart Association.

The focus of this three-day postgraduate course will be on functional pathology of valvular and pericardial diseases — congenital and acquired types.

The course will be directed by Jesse E. Edwards, M.D., Director of Laboratories at Charles T. Miller Hospital and board member of the American Heart Association. Doctors Lewis S. Carey, Robert S. Eliot, James N. Karnegis and James Ronan will be on the faculty.

The Blue Shield

Blue Shield Will Occupy New Minneapolis Office

Blue Shield of Minnesota, the state's largest medical-surgical plan, has announced its purchase of a new headquarters building at 2344 Nicollet Avenue, Minneapolis.

Thomas C. Paton, executive vice president, said the medical service organization plans to occupy the four-story building as its state headquarters July 26, 1965.

Paton said that Blue Shield's present offices at 2218 University Avenue, on the Midway in Saint Paul, will be vacated July 23. Blue Shield has maintained its quarters on the Midway since 1960, a building with approximately 20,000 square feet of floor space.

The new Blue Shield building in Minneapolis has more than 50,000 square feet of floor space, plus storage area and parking facilities, Paton said.

It was constructed in 1922 as the company headquarters of American Hardware Mutual Insurance Co., and later sold, in 1956, to the Sentry Life Insurance Co. Construction is of reinforced concrete, with exterior walls of St. Cloud granite, Indiana limestone and pressed brick. Architectural style of the building is described as "French Residence."

"In just five years, we've had such substantial progress within our organization that we needed newer and larger quarters," Paton said. "The Midway building served well and readily as our home when we first began rebuilding our service organization for both subscribers and physicians," he added.

Paton said the Blue Shield organization has had three $1 million growth years in the past three years, reaching an all-time record subscriber income in 1964 of $14.5 million. He said that Blue Shield returned nearly 90 percent of this income back to subscribers in the form of payments for their doctor or hospital bills.

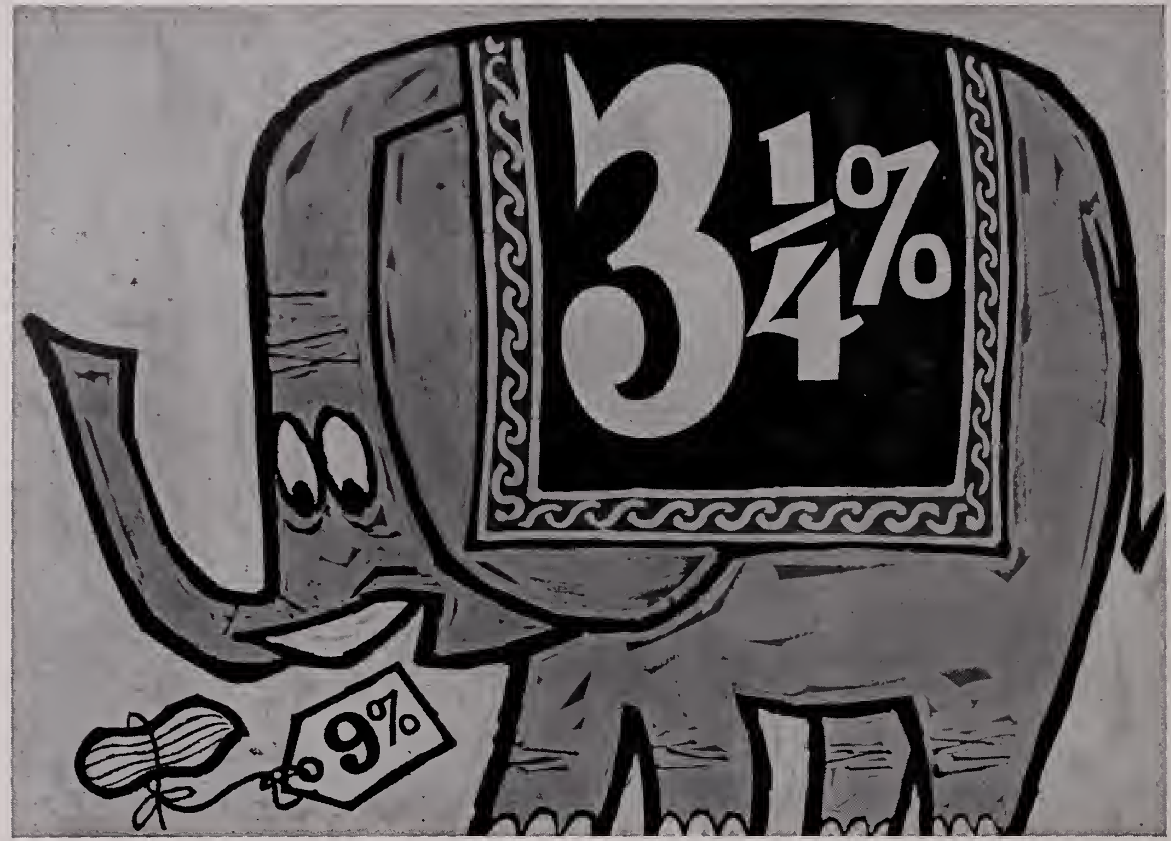
At the same time, he reported, the organization's "reserve fund" — designed to meet future emergencies — has reached the record figure of nearly $4 million. In 1960, the organization had a reserve fund of $3.5 million and had subscriber income of $11.5 million.

For its increased services Blue Shield has added greatly to its personnel roster, Paton said. He said beginning in 1960, Blue Shield had 37 employees, later boosted to around 140 by the end of the year. At the end of 1964, Blue Shield had 194 employees.

The number of physicians participating in Blue Shield has grown since 1960, according to Paton. He said that in 1960 Blue Shield was sponsored by 3,100 doctors of medicine in Minnesota, and today, Blue Shield has gained in medical sponsorship to nearly 3,300 doctors.

By all means go your own way in life. But do it in the same fashion as you go your own way down a crowded street, without stamping on other people's feet or knocking them into the gutter. — The New Age

Riddle: When is 3¼% larger than 9%?



Answer! When it represents *keepable* income from tax-free municipal bonds! A 9% yield from ordinary stocks may seem like a nice profit. But, it's really small peanuts, if you're in a high income bracket. Reason? Federal and state income taxes can take a huge amount of that profit away. Not so with *tax-free* municipal bonds! They allow you more "keepable" income . . . more big peanuts to salt away in your trunk! First National Bank offers a large selection of these bonds. Sound good? Then mail the coupon below for our free booklet "The Story Behind Municipal Bonds," as well as our handy "Tax Exempt Versus Taxable Income Table." Both give you vital information that can save you money. Or call our Investment Department (221-9463). So make like an elephant—don't forget—tax-free bonds can give you more *keepable* income!

...nothing, that is, except the

sedative-antispasmodic action of DONNATAL®

Functional disturbances of gastrointestinal tone and motility present the physician with an all too common reaction to the stressful dilemmas and frustrations of modern living.[3,6]

For their dependable control, no better spasmolytic has ever been discovered than the *natural* belladonna alkaloids in combination with phenobarbital, as in DONNATAL.

Phenobarbital, as a mild sedative, has the benefit of long use and a reassuring record of freedom from unexpected and untoward reactions. In allaying subjective tension, it helps to prevent emotional stimuli from provoking or intensifying visceral spasm.

The *natural* belladonna alkaloids in DONNATAL—conforming to the classic formulation by Vollmer[5]—selectively include only the therapeutically desired alkaloids in precisely and optimally balanced ratio. The clinical uncertainties of the variable tincture and extract of belladonna are thus avoided.

Further, a recent pharmacological study has confirmed that the antispasmodic effectiveness of the belladonna alkaloids in DONNATAL is measurably potentiated by the presence of phenobarbital.[8]

Over the years, the professional consensus has reflected broad clinical confidence in the marked benefits to be achieved by DONNATAL in a wide range of visceral disorders...in peptic ulcer,[1,6] functional bowel distress,[1] gastrointestinal spasm and discomfort,[2] and other functional disturbances of visceral smooth muscle.

CONTRAINDICATIONS: Glaucoma, advanced renal or hepatic disease or hypersensitivity to any of the ingredients.

PRECAUTIONS: Administer with caution to patients with incipient glaucoma or urinary bladder neck obstruction as in prostatic hypertrophy.

SIDE EFFECTS: Blurring of vision, dry mouth, difficult urination or flushing and dryness of the skin may occur at higher dosage levels, rarely at the usual dose.

(Warning: May be habit forming.)

Breast cancer can be highly curable if it is detected early, through regular examinations. Yet, despite all efforts in cancer education and improvements in treatment techniques in the last 30 years,

THE NUMBER OF BREAST CANCER DEATHS PER 100,000 WOMEN IN THIS COUNTRY HAS NOT DECLINED.

While research continues to seek new answers, it is imperative that greater efforts be made to detect breast cancer early and to get women to their doctors when chances of cure are best. That's why the American Cancer Society is encouraging its Divisions across the country to carry out special breast cancer educational programs. Newest of these are demonstration projects in which physicians in a community volunteer one day to giving breast examinations and to teaching hundreds of women breast self-examination. Breast cancer is one of the major cancer problems which we face and which together, doctor, we must try to resolve through intensified research and educational efforts.

AMERICAN CANCER SOCIETY

Annual Meeting Report

Varied Annual Meeting Program Attracted Considerable Physicians Interest

The Minneapolis Auditorium and the Capp Towers provided the setting for the 112th annual meeting of the Minnesota State Medical Association. Rated as one of the most significant meetings in recent years, a number of important actions were taken by the House of Delegates.

The Tuesday, May 18, scientific sessions constituted the Minnesota State Medical Association observance of the 75th anniversary of the founding of the University of Minnesota Medical School. The program included speakers of the medical school faculty and distinguished alumni of world-wide renown.

Minnesota Physicians Receive Numerous Honors

The 1965 meeting was also one at which two distinguished service award winners were announced. Recipients of the award were Drs. O. J. Campbell, Minneapolis, and A. O. Swenson, Duluth.

Winner of the Southern Minnesota Medical Association award for the best scientific exhibit prepared by an individual physician was Dr. Paul J. Bilka. The title of his exhibit was "Examination of Joints; Knee and Shoulders."

Eighteen Minnesota physicians who have practiced medicine for 50 years received 50 Club awards and citations at the annual banquet on May 18.

The following are additional highlights of the 1965 annual meeting.

House Blue Shield Actions Taken

On Sunday afternoon, May 16, the Reference Committee on Medical Economics Reports met in an open meeting to which all delegates were invited to attend. The purpose of the meeting was to consider the report of the Ad Hoc Committee to study Blue Shield. The chairman of the Reference Committee, Dr. Harry B. Hall, presided.

Delegates accepted the complete report, including a series of specific proposals for changes in the governing bodies and policies of Minnesota Blue Shield. The recommendations were adopted without change by the delegates at the closing session on May 18, following an open hearing.

The board of directors of Minnesota Blue Shield, meeting in Minneapolis the following day, took immediate action looking toward conforming to the position taken by the House.

Following is a resume of the House approved recommendations relating to Minnesota Blue Shield:

A. The board of directors

1. The board of directors of Blue Shield shall consist of eleven members chosen from the present geographic areas.

2. The term of each director shall be three-years with a maximum of three terms. This condition applies to elections occurring after 1965. Present members of the board of directors, regardless of past tenure, are eligible for an additional three terms contingent upon the age requirement (see paragraph 3 below).

3. Notwithstanding the provisions of paragraph 2 above, directors shall not hold office beyond that three-year term in which they reach the age of 65. No person who is 65 years of age or over shall be eligible to be elected a director.

4. Present board members over the age of 65 will complete their present three-year term.

5. The corporate body will nominate and elect members of the board of directors. Vote by proxy shall not be permitted.

B. The corporate body

1. New members of the corporate body are to be nominated and elected by the county or regional

Continued

medical society in the same numbers and geographic representation as the House of Delegates. The election of these corporate members shall not be subject to further confirmation.

2. Members of the corporate body shall not hold office beyond the age of 68.

The House does not believe that legislation is necessary to accomplish these recommendations, but if legislation is necessary to accomplish any of these recommendations, they request Blue Shield to initiate such legislation in 1967.

Recommendations with respect to contracts and fees:

A. The House agrees with the Ad Hoc Committee that the concept of usual and customary fees in competitive practice is recognized as the valid determinant of values of medical service.

B. The House agrees with the Ad Hoc Committee in recognizing that a review committee at the local level is essential to protect against abuses and to evaluate the value for unlisted procedures within a plan utilizing usual and customary fees.

C. The House agrees with the Ad Hoc Committee that each county or regional medical society should periodically determine the modal unit value that is being applied to the Minnesota Relative Value Index in its area.

D. Any reduction from usual and customary fee is to be negotiated at the local level as a percentage reduction or discount therefrom. Any percentage reduction will be determined by the individual circumstances of the disadvantaged person or group.

E. Contracts with the Plan A and Plan B fee schedule shall be phased out of existence as they expire. No such new contract shall be issued and no such contract shall be renewed execpt as an indemnity contract after June 30, 1966.

F. All service contracts shall be converted to the concept of usual and customary fees as soon as possible. Recognizing that business considerations may necessitate some delays in such conversion, the House requests Blue Shield to inform the House of Delgates in writing that such conversion will be put into effect as soon as practical. Any reduction from the usual and customary fee is to be negotiated as a percentage reduction or discount therefrom as determined by the individual circumstances of the disadvantaged person or group.

The House of Delegates will look critically upon any unwarranted delay and must be assured that new service contracts with any agency of government be made in observance of the usual and customary fee concept.

The Blue Shield Board is requested to report to the Council in six months and to the House of Delegates in one year with reference to its progress in implementing the above recommendations.

The House of Delegates directs the Speaker of the House to appoint a committee to evaluate the biannual and annual report of Blue Shield, and report back to this House of Delegates. This committee would also be available for consultation with the Blue Shield Board.

Non-Participation Resolution Fails

Delegates endorsed the Reference Committee recommendation that no statement of "Non-Participation" under HR 6675 or similar medicare legislation should be adopted. The action was taken in response to several non-participation resolutions submitted to the Committee. In their stead the House reaffirmed the principles of the code of medical ethics as the basis for medical practice.

The reference committee noted the following compelling considerations concerning the philosophy of non-participation:

1. Hearings concerning HR 6675 are at present being conducted in the Senate Finance Committee of the U. S. Congress.

2. A large number of amendments has already been introduced and, if adopted, may alter the form of legislation should it be enacted.

3. A statement of "non-participation" and flat rejection of the proposed legislation is untimely especially in view of our lack of information as to the final form which the bill may have if it becomes law.

4. A flat statement concerning non-participation will possibly react adversely on opportunities now available to modify favorably the form of any legislation enacted.

The Reference Committee considered that clarification of the doctor-patient relationship could well be presented at this time.

The care of the patient may well involve medical, economic, and religious concepts. The adherence to rigidly dictated terms of treatment might prove detrimental in the personal and medical management of the patient.

The Committee further noted that the Minnesota State Medical Association continues to endorse the concept of allowing the individual physician to employ those acceptable medical techniques and to participate in programs and in patient treatment which are in the best interest of his patient and which are consistent with the doctor's social, religious, and medical training.

The Reference Committee impressed its awareness of the mixed attitudes and emotions held on this resolution but felt the Committee's statement reflected a consensus of opinion.

Usual and Customary Fee Principle Adopted

In another far-reaching action the House adopted unanimously a Council resolution urging Minnesota State Medical Association members to use the usual and customary fee as the basis for all negotiations with any third parties seeking to purchase service medical care for their subscribers, members, or clients.

The resolution observes:

The public has repeatedly sought and continues to seek prepayment mechanisms which cover virtually all medical expenses. The only effective mechanism evolved to date which fulfills this goal and at the same time allows freedom of choice of physicians is the prepayment plan with premium structure geared to payment of the usual and customary fee.

Such plans are presently functioning well elsewhere, both for nonprofit underwriters, such as Blue Shield, and for commercial companies.

There are presently three programs functioning successfully in Minnesota on the usual and customary fee basis, namely, the military dependents Medicare program, the Social Security Disability Determination program, and the Blue Shield "J" Plan sold exclusively on the range.

The sine qua non for success of all usual and customary fee plans has been a conscientious Review Committee at the local level to protect against abuse of the plan.

The only valid determinant of what a given unit of medical service is worth is the usual and customary fee of the physician in competitive practice.

Any reduction from the usual and customary fee will in the future be negotiated on a local level as a percentage reduction or discount. Any percentage reduction will be determined by the individual circumstances of the disadvantaged person or group.

The resolution also states that a medical review committee is to be established immediately in each county medical society to determine annually the modal unit value applied by its members to the Minnesota Relative Value Index. This Committee will also review fees referred to it by any individual or third party requesting such a review.

Copies of this resolution have been sent to all Minnesota State Medical Association members with the June, 1965, Minnesota Newspage.

In accordance with the directives of the resolution, copies have also been sent to the Director of Blue Shield, the Governor's Medical Advisory Committee and the Minnesota Commissioner of Welfare.

Additional Actions Listed

Other matters considered by the House of Delegates included: a resolution from the Renville-Redwood County Medical Society on the DeBakey report opposing the report as a proposal to replace the American system of private medical care with government medicine and directing that the position of the association be sent to the committee of the AMA which is evaluating the report; approval of a proposal from the Public Health Education Committee for a public and physician education campaign emphasizing the importance of protection against tetanus; approval of the recommendation made by the Range County Medical Society for 17 safety features in the manufacture of automobiles as set out in Federal Law PL 88-515 as a measure of controlling death rates on the highways.

Approved a Public Health Education program to emphasize the importance of wearing the AMA Emergency Medical Identification Symbol and the importance of using personal health record cards which provide personal health information including allergies, immunizations, epilepsy, diabetes, and etc.

The delegates rejected a resolution which objected to the confidential section of the birth certificate which gives essential morbidity information as to malformations, Rh

Continued

status and other conditions. In so doing, the delegates went on record in favor of this invaluable means of making available otherwise indispensable information for morbidity and mortality studies.

New Officers Named

Dr. R. P. Buckley, Duluth, was named president-elect at the closing session of the House. Other officers elected were: Dr. Harry B. Hall, Minneapolis, first vice president; Dr. O. L. N. Nelson, Minneapolis, second vice president; Dr. Barnard Hall, St. Paul, secretary (re-elected); Dr. Karl W. Anderson, Minneapolis, treasurer (re-elected); Dr. John T. Pewters, Minneapolis, speaker of the House; Dr. Leon E. Steiner, Albert Lea, vice speaker of the House.

Councilors: Dr. G. R. Diessner, Rochester, First District; Dr. Walter B. Wells, Jackson, Second District (re-elected); Dr. Florian H. Baumgartner, Albany, Seventh District; Dr. John H. Peterson, Duluth, Ninth District. *AMA Delegates:* (3 to be elected) Dr. O. J. Campbell, Minneapolis; Dr. John L. Falls, Red Wing; Dr. A. E. Ritt, St. Paul (re-elected).

AMA Alternates: Dr. J. P. Medelman, St. Paul; Dr. Haddon M. Carryer, Rochester; Dr. Donald McCarthy, Minneapolis; Dr. Walter B. Wells, Jackson. Dr. George Sather, Fosston, is the newly elected chairman of the Council.

University of Minnesota Given AMA-ERF Gift

A check of $16,564.64 was given to the University of Minnesota Medical School at the opening session of the House of Delegates. This is a grant from the AMA-ERF, and it represents the gifts to the University of Minnesota by physicians. It is part of the record $1,313,559.31 contributed in 1964 for medical schools by physicians and their families throughout the country. David A. Pope, a University of Minnesota Medical School freshman from Janesville, Minnesota, was introduced as the 1965 recipient of the Rural Medical Scholarship.

St. Paul was named the host city for the 1966 annual meeting.

AMA President Urges Minnesota Physicians to Continue Medicare Opposition

AMA president, Dr. Donovan F. Ward, was a distinguished guest and speaker at the 112th annual meeting of the Minnesota State Medical Association. A practicing surgeon from Dubuque, Iowa, Dr. Ward is well known to many physicians in the North Central Conference area.

On Monday evening, May 17, Dr. Ward was the speaker at the annual banquet of the Minnesota Academy of General Practice held in the Minneapolis Capp Towers, Hall of Flags.

On Tuesday morning he addressed the House of Delegates at the closing session.

Because of the significance of his remarks, the text of his address to the delegates has been reproduced on the following pages:

"On May 11, the American Medical Association did testify before the Senate Finance Committee on HR-6675; as you well know, the Social Security amendments of 1965. This hybrid bill of overwhelming proportions was passed by the House of Representatives April 8, after a brief debate and without public examination or discussion in the House Ways and Means Committee.

"This proposal, complicated, costly, and containing ominous implications for the nation's economy and health-care system, is the most far-reaching, omnibus bill ever to come before the House in the last 30 years. It would add a compulsory hospitalization plan to the Social Security system, a system which heretofore gave beneficiaries cash dollars instead of benefits. It would authorize a federally-subsidized program of health insurance to cover the medical, surgical, and drug bills. It would expand the present Kerr-

Mills law to cover dependent children, the blind, and disabled persons. It would include self-employed physicians under Social Security. It would increase Social Security cash benefits, give benefits for widows at age 60, amend the disability program liberalize the earned-income limitation into a retirement test, cover cash tips as wages, exempt certain religious sects from Social Security, and do many other things.

"Some of the provisions and objectives of this omnibus bill are good and worthy. Unfortunately, they have been thrown into a conglomerate package which includes a watered-down version of the tired old King-Anderson proposal to provide a limited hospital coverage for everyone over 65, regardless of their need or income; and it would provide it at a cost of a greatly increased tax on the working man and woman. As far as anyone can tell at the present moment, this legislation will cost an approximate 6.6 billion dollars in its first year of operation. To finance the eventual cost, which actually is unpredictable, the bill will raise both the Social Security tax rate and the taxable wage base in a series of increases over the years to come. It will raise the annual Social Security taxes of wage earners and employers from the present maximum of $174 each to $243.60 in 1966, for an increase of $69.60. It will raise the same tax to $369.60 on the employe and $369.60 on his employer by 1987, if we are lucky; and this is more than double the present maximum.

"I quote verbatim from a part of the testimony that the AMA presented before the Senate Finance Committee: 'HR 6675, if enacted into law, will affect the lives of all who live today and the lives of our children and our childrens' children. HR 6675 will introduce into our way of living an entirely new concept of social welfare. HR 6675 will alter the structure of our medical-care system for generations to come.

" 'In the face, then, of so vital a statement, should you not once more pause and consider? You are familiar with the inscriptions on the National Archives Building, which read: 'What is past is prologue,' and study the past to try to gain a glimmering of the shape of things that will tend as a direct result of the action you are being asked to take? Let us examine the past. Let us look for a moment at the government medical systems in other parts of the world. Have national medical schemes resulted in medical help or economic gains? Has the health of the public improved or made gains which surpass those in our country? Has medical science advanced in countries with socialized medical schemes? Have there been economic gains to their people? The answer is no to all these questions. There is nothing in the history of nationalized medical care systems which can lead us to believe, to hope our experience will be unique, and we can hope for no better results here.'

"I also asked the Senate Finance Committee last week: 'Forget for a moment the staggering, though unpredictable, cost of the present program. Ignore the administrative problems that it would create and the burdens it would create for wage earners at the low end of the income scale. Look only at the intrusion of government in the field of medicine, which cannot be avoided if this measure is adopted. With the quality of care thus restricted for the sake of controlling costs, the quality must deteriorate. The patient is the ultimate sufferer. Look again at the experience of foreign programs. The adoption of HR 6675 will set a pattern difficult in the extreme to reverse.' This program cannot be tried out and easily canceled if it proves unsatisfactory. This may be our last chance to ask you to write legislation which will meet the nation's needs, and at the same time avoid the pitfalls of government-financed, government-controlled, and government-oriented health-care systems. This may be your last chance. Weigh the consequences of taking the first step in the establishment of socialized medicine in the United States. While there is still time, we urge you to pause and consider; and here this morning I repeat that plea, and I urge you to repeat it to all the members of the United State Senate. We ask for careful consideration of the Eldercare program, sponsored and supported by the AMA, and favored by an overwhelming majority of the American people.

Continued

"Some may say that it's too late; we should quit; we should not fight against such overwhelming odds. All that I can think of is one of the tunes of the musical, THE UNSINKABLE MOLLY BROWN, 'I Ain't Down Yet.'

"I would like to report to you that I have never seen such cohesion and unity amongst the medical profession. Cohesion is an individual effort; unity is an individual effort. And I must say that the members of the American Medical Association are a cohesive unified body.

"I think I could possibly end this by giving you my idea of how I feel about it by saying a little quote that I sometimes remember from Shakespeare, and it goes thus: 'Lay on, McDuff, and damned be he who cries, Hold, enough.' And I say that we should lay on, and perhaps we might get our way; and perhaps the administrators, the legislators, might say, 'Hold, enough': and that we can win if we will stay in there and pitch."

Remarks of J. M. Stickney, M.D., President of Minnesota State Medical Association, to the House of Delegates — Sunday, May 16, 1965

As the president of your association, it is a challenging and rewarding experience to meet with medical groups and our allied professions in this state and with the medical societies of our neighboring states. Although the president seldom has a major part in making policy, he is constantly asked to explain and interpret the policies which you and the council determine. A review of the president's role in the more than one-hundred years of our existence brings many interesting facts to light. In earlier years he presided at the general convention, and with the formation of the House of Delegates, he became the presiding officer until a revision of the constitution in 1938 established the speaker. Presidential addresses have been delivered before the association in scientific session, at the annual banquet and in recent years before this House. The rather eloquent essays of an earlier time, filled with literary references, have more lately become what might be called remarks appropriate to the day. One is impressed with the fact that many of the problems which earlier presidents considered important enough to discuss are still with us. Always there has been the concern about the best possible medical care for the people of Minnesota, a theme which we hope will never disappear. High ethical and moral standards of intra-professional and public relations were recurrently discussed. The convention of 1869, which entitled itself The First Annual Meeting, adjourned with a request for the members to go home and enumerate the irregular practitioners as compared to the fully qualified and to report on ways of eliminating inferior practice. This intense desire of our predecessors has made Minnesota an outstanding state in the regulation of medical practice. In 1909 Dr. Cornelius Williams made a plea that doctors be paid the same proportion of their charges that the merchants received for their prices from charity patients, and in the 1920's the call to participate in political life lest the medical profession be engulfed by government was repeatedly sounded. We have an adage at the Mayo Clinic that a good solution for many problems faced by a committee may be found by reading the minutes of 10 years ago, and often it is surprisingly true.

Just as we face many problems which have remained unsolved through the years, so do we find that today ours are similar to those of the profession in the neighboring states. I recently had the privilege of visiting the Iowa House of Delegates while they urged "Full and Reasonable Fees" from their Blue Shield organization.

Through the years, crisis after crisis has arisen and the profession has moved forward, often with change, but with integrity and accomplishment. Perhaps the year 1965 represents one of the greatest of the crises. At this moment the details of a new concept in the management of the health care of a whole segment of our population are under discussion before a committee of the Senate. Whether Medicare becomes law or not, we may be sure that a new era is emerging. Hospital administration, voluntary prepayment service or private insurance plans, and probably government are to be our full partners in health care, and with each we must work to produce what only a physician can render, namely good medical care. If, in spite of our efforts to modify Medicare, the law is passed in its present form, we have no choice but to provide the best service we can and to labor to accomplish desirable changes. In our dilemma we must not ignore the other partners aside from government, lest they become our masters rather than our partners. Never before in the years of our cooperation with our medical service associations, Blue Cross and Blue Shield, has it been so necessary that we work with them on friendly intimate terms and they with each other; that we must have our relations with Blue Shield in such order that we can, without reservation, approve it as the Doctor's Plan.

There are many factors in medical practice today which demand that our liaison with the Medical School of the University be close and cordial. There are differences in viewpoints which are inherent in the essential task which the educator and the practitioner face. Each should be understanding of the other's problems, and to this end there is an opportunity for the state medical association to be of service. There is a tendency to place the problem of obtaining physicians to do family practice in the lap of the educator, but I would observe that it is equally the responsibility of the practicing profession to define and create a realistic opportunity for satisfying family practice which will dictate what kind of undergraduate and graduate preparation is essential. The wholesome relationship between educators, specialists and family doctors is an essential ingredient in a healthy state medical association. Agencies sponsored by government and others have suggested a mobilization of resources for research and better patient care which, if implemented, would most certainly involve medical centers and the practitioners throughout the state. Voluntary accomplishment in a sound and progressive program encompassing both research and the practical aspects of medical care will serve to direct future patterns along lines more acceptable to all.

To assure the continued success of the annual meeting it will require persistence and some ingenuity together with cooperation of all sections of the profession. It is the responsibility of this House to determine what type of meeting will meet our needs and how it shall be financed. Better attendance at the scientific sessions and the commercial exhibits is essential if the present format is to continue.

You may wish to give some consideration to making the president's term of office coincide with the year between annual meetings and to the selection of a president-elect for the same period.

It has been a pleasure to serve as your president during the first portion of this term, and I pledge my continued efforts on your behalf in the remaining months. I sincerely thank you and the council for your splendid co-operation and special thanks go to Mr. Brunn, Mrs. Fitzgerald, and the state office staff.

You are invited to send your abstracts to the Abstract Section of Minnesota Medicine, 496 Lowry Medical Arts Building, St. Paul, Minnesota, 55102. Your name and address will be withheld or listed, whichever way you desire.

In Appreciation

The Minnesota State Medical Association would like to express its appreciation to the firms listed below. These firms were technical exhibitors during the recent 112th Annual Meeting of your Association. Their participation in our annual meeting contributed much to its success.

In Memoriam

To be ambitious of true honor and of the real glory and perfection of our nature is the very principle and incentive of virtue; but to be ambitious of titles, places, ceremonial respects, and civil pageantry, is as vain and little as the things are which we court. — Sir P. Sidney

ARTHUR F. BRATRUD, M.D.

Dr. Arthur F. Bratrud, 78, retired Minneapolis surgeon and former president of the Minnesota Conservation Federation, died May 31st. He was born in Fountain, Minnesota and graduated from the University of Minnesota Medical School. Dr. Bratrud practiced medicine with his brother, the late Dr. Theodore Bratrud, in Warren, Minnesota, served in World War I and practiced surgery in Minneapolis from 1920 to 1963.

He was a fellow in the American College of Surgeons and a member of the American Medical Association and Hennepin County Medical Society. Dr. Bratrud was also a 50 Club and life member of the Minnesota State Medical Association.

He is survived by his wife and a daughter.

MARTIN ALBERT NORDLAND, JR., M.D.

Dr. Martin Albert Nordland, Jr., 44, Minneapolis surgeon, collapsed while playing golf on May 30, and died at the golf club shortly thereafter. He was born in Minneapolis and received his medical degree from the University of Minnesota.

Dr. Nordland was a fellow in surgery of the Mayo Graduate School of Medicine from 1945 to 1948 and later left the Clinic to join his father, Dr. Martin Nordland, Sr., in the practice of surgery. He was a member of the surgical staff of the Northwestern Hospital, and a fellow of the American College of Surgeons, member of the American Medical Association, Minnesota State Medical Association, Hennepin County Medical Society, Nu Sigmu Nu professional medical fraternity and the Alumni Association of the Mayo Graduate School of Medicine.

He is survived by his wife and three children.

JALMAR H. SIMONS, M.D.

Dr. Jalmar H. Simons, 80, Minneapolis specialist in gynecology and obstetrics, died June 6th. He was born in Minnesota and received his degree in medicine from the University of Minnesota.

Dr. Simons was a member of the faculty of the University of Minnesota school of medicine for the last sixty years, was on the staff at St. Barnabas Hospital and a department head of Hennepin County General Hospital. He served two terms as president of the Hennepin County Medical Society and was a member of the American Medical Association. He was a 50 Club and associate member of the Minnesota State Medical Association.

He is survived by his three daughters and three sons.

Hygroton®
brand of chlorthalidone

the long-acting diuretic

Indications: Many types of edema involving retention of salt and water.
Contraindications: Hypersensitivity and most cases of severe renal or hepatic disease.
Precautions: Reduce dosage of concomitant antihypertensive agents by at least one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take special care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.
Side Effects: Agranulocytosis, constipation, dizziness, dysuria, headache, hyperglycemia, hyperuricemia, impotence, leukopenia, muscle cramps, nausea, postural hypotension, purpura, thrombocytopenia, transient myopia, urticaria, vomiting and weakness.
Average Dosage: One tablet (100 mg.) daily with breakfast.
Availability: Tablets of 100 mg. in bottles of 100 and 1000.
For full details, see the complete prescribing information.

lygroton®
and of chlorthalidone

In terms of sodium excretion, 2 tablets of Hygroton®, brand of chlorthalidone, are significantly more potent than 4 tablets of chlorothiazide, and also more potent—though not significantly—than 4 tablets of hydrochlorothiazide.* Thus, tablet for tablet, you can expect more from Hygroton, brand of chlorthalidone. Especially since it acts for up to 72 hours. You can prescribe fewer tablets at wider intervals than with any other diuretic.

GERIATRIC SYNDROME

when a change in environment overwhelms him with anxiety

Failing health, financial difficulties, or the death of a spouse are among the reasons why elderly people may be obliged to leave their familiar surroundings. Moving in with children or entering a home for the aged may satisfy practical requirements but can be psychologically traumatic since emotional resilience tends to diminish with age.

Even when anxiety reaches overwhelming proportions, you can counteract it promptly with the potent tranquilizer—Atarax (hydroxyzine HCl).

The outstanding systemic safety record of Atarax makes it particularly suitable for geriatric patients whose drug tolerance is often low. The usual initial dosage in such patients is 50 mg. q.i.d. However, this tranquilizer is so well tolerated that dosage can be adjusted to meet individual requirements. The wide variety of dosage forms allows flexibility of administration from any standpoint—convenience, patient preference, or emergency requirements.

No age, of course, is exempt from anxiety and any number of circumstances can unleash it. Keep Atarax in mind for *all* your emotionally distressed patients—from under 6 to over 60.

for any age—for any stage of anxiety

Rx ATARAX®

(hydroxyzine HCl) tablets syrup parenteral

...In any condition where tissue depletion of the water-soluble vitamins is found, Rx **RoeriBeC**® therapeutic B complex with 500 mg. of vitamin C.

J. B. Roerig and Company
Division, Chas. Pfizer & Co., Inc.
Science for the World's Well-Being®
New York, New York 10017

Side effects and precautions: The transitory drowsiness which may occur with hydroxyzine HCl usually disappears spontaneously in a few days with continued therapy, or is correctable by dosage reduction. Dryness of the mouth may be seen with higher doses. Involuntary motor activity has been reported in hospitalized patients on higher than recommended doses. Hydroxyzine HCl may potentiate CNS depressants, narcotics such as meperidine, barbiturates, and anticoagulants. In conjunctive use, dosage for these drugs should be decreased. Because drowsiness may occur, patients should be cautioned against driving a car or operating dangerous machinery. **Parenteral Solution Precautions and contraindications:** This dosage form is intended only for I.M. or I.V. administration and should not, under any circumstances, be injected subcutaneously or intra-arterially. When the usual precautions for I.M. injection have been followed, reports of soft tissue reactions have been rare. I.V. administration should be slow, no faster than 25 mg. per minute, and should not exceed 100 mg. in any single dose. Particular care should be used to insure injection only into intact veins; a few instances of digital gangrene occurring distal to the injection site have been attributed to inadvertent intraarterial injection or periarterial extravasation, both of which should be avoided. **More detailed professional information available on request.**

nicotron™ Nicotinic Acid and Aminoacetic Acid (Glycine)

Like Radiant Sun

Warms Cold Hands and Feet

nicotron™
NICOTINIC ACID +
AMINOACETIC ACID (Glycine)

increases and sustains peripheral blood flow (1-2)

INDICATIONS: Poor circulation causing cold hands and feet or pain on walking. For the more serious peripheral vascular disturbances such as . . . Raynaud's Disease, Meniere's Syndrome, intermittent claudication, diabetes, post-phlebitis syndrome, leg ulcers due to venostasis and chronic thrombophlebitis.

DOSAGE: 1 or 2 teaspoonfuls or 1 or 2 tablets 3 times a day before meals. The feeling of warmth and tingling of the skin is a desirable effect. If this reaction is too pronounced reduce dosage.

CONTRAINDICATIONS: There are no known contraindications.

SUPPLIED: 8 oz. bottles and bottles of 100 chew-tabs.

FORMULA: Each teaspoonful (5ml.) elixir or each chew-tab contains:

Nicotinic Acid	75 mg.
Aminoacetic Acid (Glycine)	750 mg.

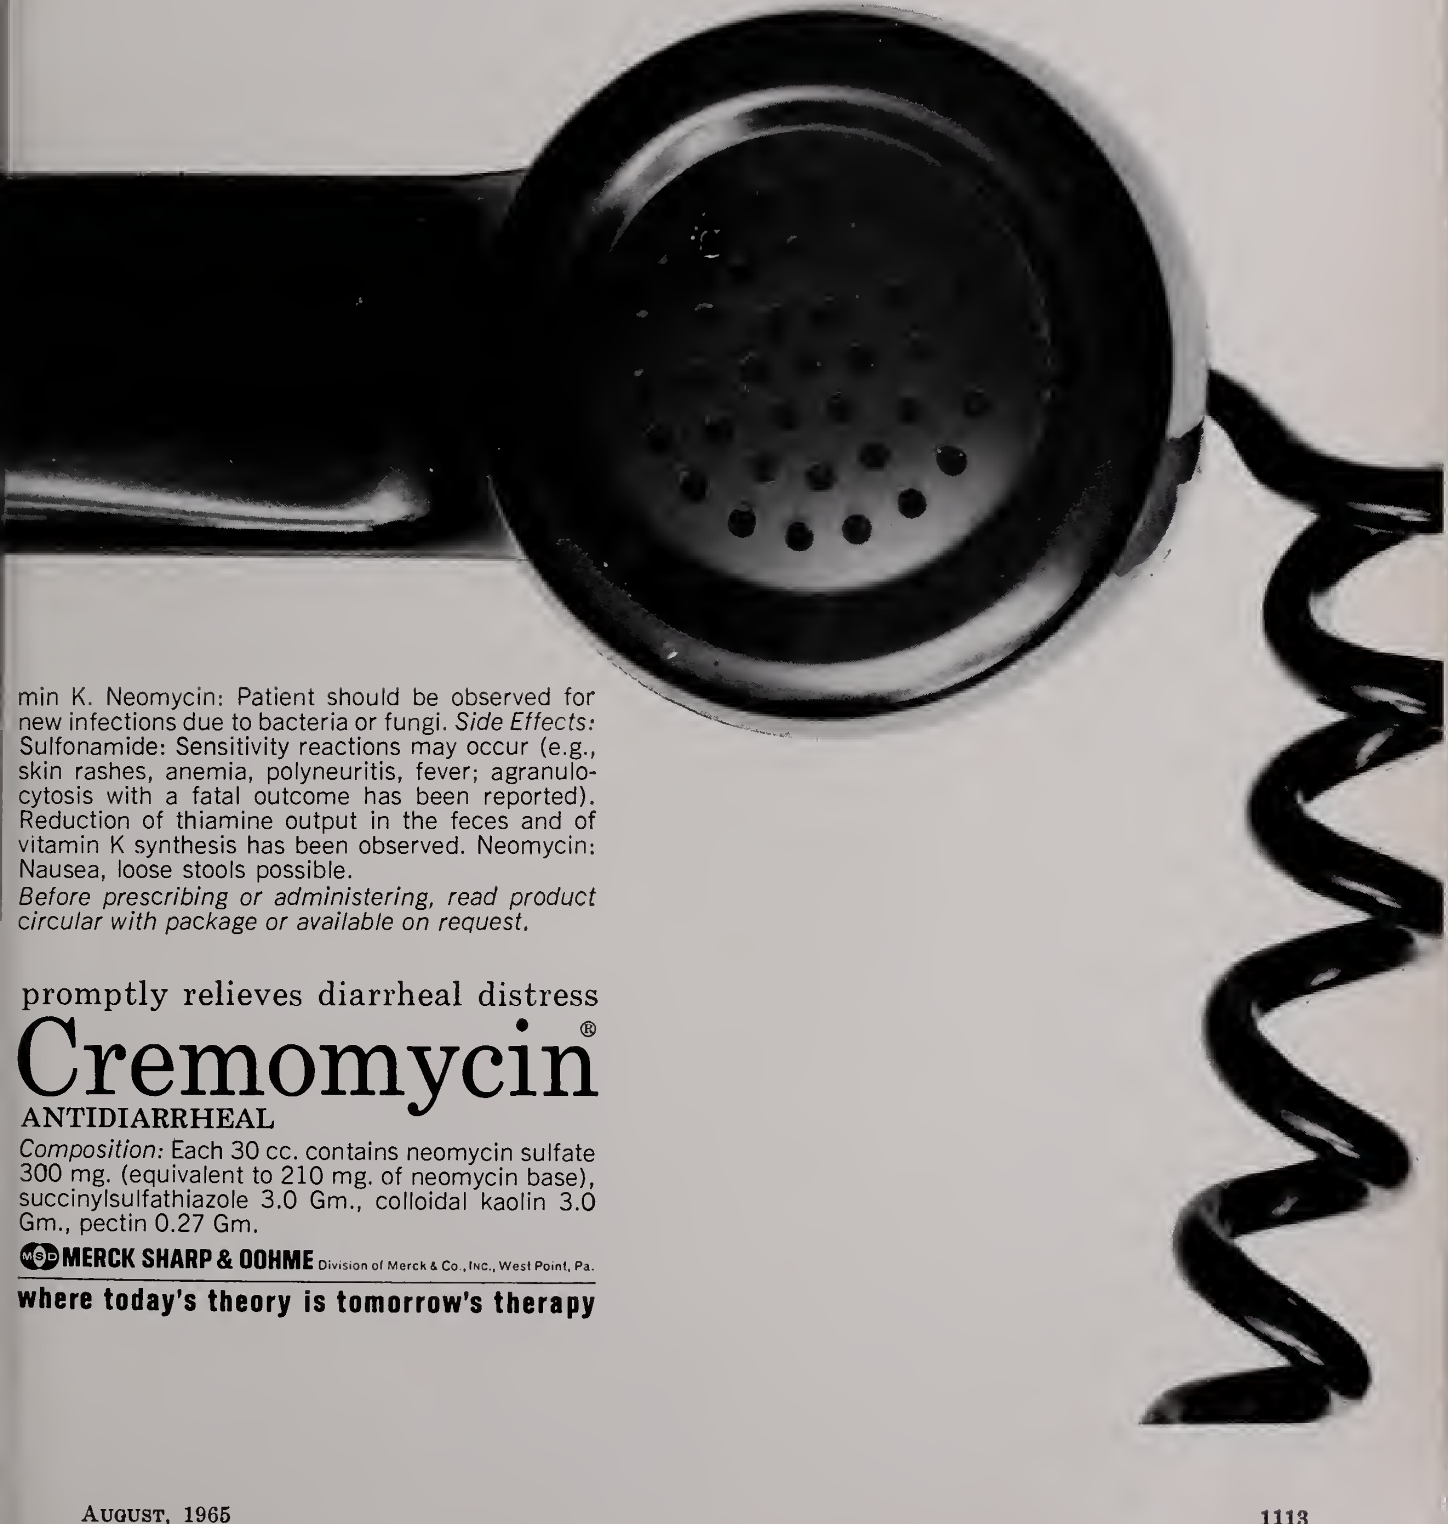
When uncontrolled diarrhea brings a call for help

When the diarrhea sufferer has run the gamut of home remedies without success, pleasant-tasting CREMOMYCIN can answer the call for help. It can be counted on to consolidate fluid stools, soothe intestinal inflammation, inhibit enteric pathogens, and detoxify putrefactive materials—usually within a few hours.

CREMOMYCIN combines the bacteriostatic agents, succinylsulfathiazole and neomycin, with the adsorbent and protective demulcents, kaolin and pectin, for comprehensive control of diarrhea.

Indications: Diarrhea. *Contraindications:* Kaolin: Withhold if diverticulosis is present or suspected. *Precautions:* Sulfonamide: Continued use requires supplementary administration of thiamine and vita-

your ℞ for
Cremomycin
can provide relief



min K. Neomycin: Patient should be observed for new infections due to bacteria or fungi. *Side Effects:* Sulfonamide: Sensitivity reactions may occur (e.g., skin rashes, anemia, polyneuritis, fever; agranulocytosis with a fatal outcome has been reported). Reduction of thiamine output in the feces and of vitamin K synthesis has been observed. Neomycin: Nausea, loose stools possible.

Before prescribing or administering, read product circular with package or available on request.

promptly relieves diarrheal distress

†Requirement in human nutrition not yet established

the need for a tonic knows no age

Anyone can feel tired and "old" too soon. In such functional fatigue, Alertonic helps to lift mood, revive interest, restore purposeful activity promptly. Yet it contains no MAO inhibitors, no hormones. Alertonic is the effective formulation of a cerebral stimulant (pipradrol hydrochloride), alcohol, vitamins, and minerals ... available on prescription *only*. For common functional complaints (mild mood depression, tiredness); geriatric or convalescent patients, Rx one *tablespoonful* Alertonic *t.i.d.*, thirty minutes before meals. Contraindicated in agitated pre-psychotic patients, paranoia, or other patients in whom hyperexcitability, anxiety, chorea, or obsessive-compulsive states are present. Mild central stimulant side effects may occasionally occur.

NTZ Nasal Spray relieves hay fever symptoms on contact

Fast symptomatic relief from seasonal hay fever comes in the convenient NTz Nasal Spray bottle. Two sprays quickly relieve itching and decongest the nasal membranes on contact. The first spray of NTz shrinks the turbinates, helps restore normal nasal ventilation and breathing. After a few minutes a second spray enhances sinus ventilation and drainage.

NTz Nasal Spray reduces excessive rhinorrhea without unpleasant dryness. It is well tolerated by delicate respiratory tissues. NTz also provides relief in head colds, perennial rhinitis and sinusitis.

NTz's carefully balanced formula relieves three ways: with a decongestant, a topical antihistamine, and an antiseptic wetting agent.

Neo-Synephrine® HCl 0.5%, a decongestant of unexcelled efficacy to shrink nasal membranes.

Thenfadil® HCl 0.1%, a topical antihistamine to help relieve itching.

Zephiran® Cl 1:5000, an antiseptic wetting agent to promote the rapid spread of components to less accessible nasal areas.

NTz is supplied in leakproof, pocket-size, spray bottles of 20 ml. and in bottles of 30 ml. with dropper.

Winthrop Laboratories, New York, N. Y. 10016

GENERAL INFORMATION

Authors

Manuscripts for consideration in Minnesota Medicine should be addressed to Office of Publication, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102. Papers should be typed double spaced on white paper with a wide margin. The first page should list the title, the name of the author (or authors), degree, and any institutional or other credits. Pages should be numbered consecutively. Tables should be typed and numbered and should have a brief descriptive caption.

Bibliographical references should be limited to twelve and should be typed in conformity to the method used by the Index Medicus. They should be numbered consecutively in the order in which they first appear in the text. Book references should give the name of the author, title, edition number, publisher, and the year.

Illustrations (photographs, tables, and graphs) should be submitted on separate sheets of paper and not combined in the text. Instructions for combining photographs are acceptable.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association of any of its constituents.

a working analgesic for the working arthritic

Arthralgen® rapidly relieves early morning stiffness and arthritic pain. It promises a quicker response in most patients because its analgesic ingredients need no metabolic conversion before they act. Combining two better-tolerated, time-tested analgesics, acetaminophen and salicylamide, into a pharmacologically sound and therapeutically effective formulation, Arthralgen relieves pain rapidly with less likelihood of gastric irritation than aspirin.

in maintenance therapy . . .

Because it contains no sodium, Arthralgen is often a safer and more suitable analgesic for use in the long-term treatments of arthritic patients who have other conditions which require sodium restriction.[1]

Arthralgen®

Each tablet contains:

Salicylamide	250 mg.
Acetaminophen	250 mg.
Ascorbic acid (Vitamin C)	25 mg.

Arthralgen®-PR

(Arthralgen with prednisone 1 mg.)

BRIEF SUMMARY:

Arthralgen and Arthralgen-PR are indicated in the management of rheumatoid arthritis, acute gouty arthritis, rheumatoid spondylitis, osteoarthritis, bursitis, fibrositis, and neuritis. Arthralgen may be used for analgesia in colds, flu, and various myalgias.

CONTRAINDICATIONS: Hypersensitivity to any ingredient.

As with any drug containing prednisone, Arthralgen-PR is contraindicated, or should be administered only with care, to patients with peptic ulcer, tuberculosis, nephritis, diabetes mellitus, acute psychoses, Cushing's syndrome (or Cushing's disease), overwhelming spreading (systemic) infection, or predisposition to thrombophlebitis.

Arthralgen-PR is generally contraindicated in patients with uremia and viral infections, including poliomyelitis, vaccinia, ocular herpes simplex, and fungus infections of the eye. It is also contraindicated in patients with chickenpox or susceptible persons exposed to it.

PRECAUTION: Reduction in dosage of Arthralgen-PR given over a long period should be gradual, never abrupt.

SIDE EFFECTS: Nausea, GI upset, or mild salicylism may rarely occur. Symptoms of hypercorticoidism dictate reduction of dosage of Arthralgen-PR.

DOSAGE: One or two tablets four times a day. After remission of symptoms dosage should be reduced to the minimum maintenance level.

President's Letter

The deliberations and actions of the House of Delegates at the 114th Annual Convention of the American Medical Association have become history. There was naturally much professional and lay interest in those matters which pertained to political and economic problems such as non-participation in government programs and the relationship of the AMA to the administrative departments of government. Never before has so much been written about one meeting. Within a few days after its close the official summary by the AMA and the many accounts appearing in the "free" journals and medical newspapers provided up-to-date information. News on this front moves too rapidly to be a fit subject for a letter such as this.

I would like to call your attention, however, to one reference committee report which resulted in postponed action on an important subject to allow time for further consideration. This report dealt with the findings of the Committee to Study the Organization of the House of Delegates headed by past president Gunnar Gundersen. Perhaps my interest was heightened because it was my assignment as a Delegate to chair the reference committee which considered the report of the Gundersen Committee. During the lengthy and sometimes heated discussions it was apparent that we were dealing with an analysis of most of the important functions of a federation such as the AMA. Changes were recommended which would streamline the delegation of authority by the policy-making House of Delegates to its elected Board of Trustees. It was emphasized that the Board must be free to act rapidly enough at all times to be in tune with current issues. To this end, it has been suggested that the Council on Medical Service be responsible to the Board rather than to the House. This council concerns itself with medical-economic problems and has developed what many think is a cumbersome system of subcommittees.

The Gundersen Committee also offers pertinent comment on the relations of the scientific sections of the AMA and the House of Delegates. Each member of the AMA belongs to one of these sections. It was pointed out that the sections are responsible to no unit within the AMA that has jurisdiction over policy. Much attention was also paid to the Council on Medical Education and its proper concern with issues such as the purposes of a medical school, the supply of physicians, and the financing of medical education.

Other items to which the Gundersen Committee gave its attention included the size of the House of Delegates with a suggested limit of 250, the tenure of trustees, and a simplification and clarification of the official policies of the AMA as recorded in the actions of the House and Board of Trustees over many years.

It is my opinion that streamlined organization will not in itself provide a mechanism which will eliminate the stalemates and delays which seem to characterize a professional group as diverse as medicine is, but this thought-provoking report should not be laid on the shelf. Some of the pertinent sug-

a significant price decline in the cost of V-Cillin K®

V-Cillin K now costs approximately 21 percent less. This significant price decline constitutes a substantial saving and still offers these important benefits over penicillin G:

The effectiveness of intramuscular penicillin. Just three 250-mg. doses daily provide total twenty-four-hour penicillin blood levels equal to those achieved by injection of 600,000 units of procaine penicillin G. A fourth dose increases daily penicillemia to levels 35 percent above those achieved by injection.

Consistent dependability—even in the presence of food. Comparative pharmacologic data show that V-Cillin K produces peak blood levels *twice* as high as those of penicillin G, with *half* the dose.

New, thin coating . . . new size and shape. The new coating eliminates the characteristically bitter taste of oral penicillin and makes V-Cillin K tablets easy to swallow. The new shape makes them easy for physicians and pharmacists to identify.

Indications: V-Cillin K is an antibiotic useful in the treatment of streptococcus, pneumococcus, and gonococcus infections and infections caused by sensitive strains of staphylococci.

Contraindications and Precautions: Although sensitivity reactions are much less common after oral than after parenteral administration, V-Cillin K should not be administered to patients with a history of allergy to penicillin. As with any antibiotic, observation for overgrowth of nonsusceptible organisms during treatment is important.

Usual Dosage Range: 125 mg. (200,000 units) three times a day to 250 mg. every four hours.

Supplied: Tablets V-Cillin K, 125 or 250 mg., and V-Cillin K, Pediatric, 125 mg. per 5-cc. teaspoonful, in 40, 80, and 150-cc.-size packages.

V-Cillin K®

Giant Russell Bodies

• in
• Neoplastic Cells
• in a
• Case of
• Leukemic
• Lymphosarcomatosis

EMIL MARO SCHLEICHER, Ph.D.*
Minneapolis, Minnesota

RUSSELL BODIES in neoplastic lymphoid cells have been reported.[1-4] Giant Russell bodies in neoplastic cells in leukemic lymphosarcomatosis, however, seem to be rare. No comparable report was found in the literature.

It is the purpose of this communication to present a case of malignant reticuloma of the lymphosarcoma type in leukemic phase with one to five and more intracytoplasmic giant Russell bodies in neoplastic cells in the primary gastric tumor, lymph nodes, liver, spleen, lungs, small bowel, mesentery, bone marrow, and the peripheral blood as demonstrated by cytochemical methods.

Case Report

A white female, 76 years of age, was admitted to St. Barnabas Hospital on March 9, 1964, with profuse hematemesis, abdominal pain and shock. Blood pressure was 120/70, pulse 94 per minute, respiration 20 per minute, and temperature $100.^2$ degrees. In August 1963 she had had a partial gastric resection at another hospital for a malignant neoplasm interpreted as an "anaplastic carcinoma."

Laboratory Studies and Progress

Hemoglobin 8.5 grams per cent, white blood cell count 5,200, differential leukocyte ratio, stab forms 19, polymorphonuclears 46, lymphocytes 19, monocytes 13, eosinophils 1, basophils 1, plasma cells 1 per cent. Thrombocytes 120,300/c.mm. The morphology of the erythrocytes was suggestive of chronic hypoferremia. Roentgenogram of the chest showed a nodular density in the left lower lobe. Metastatic disease was considered. She received five units of whole blood raising the hemoglobin to 10.3 grams per cent. She was discharged on April 2, 1964.

She was re-admitted on April 9, 1964, in a lethargic and dehydrated state. Her abdomen was distended and various sized areas of ecchymoses were present on the upper extremities and the buttocks. No visible jaundice. No gross loss of blood.

Hemoglobin 7.4 grams per cent, white blood cell count 12,400, differential leukocyte ratio, metamyelocytes 1, stab forms 5, polymorphonuclears 10, lymphocytes 4, monocytes 4, neoplastic lymphoid cells with intracytoplasmic giant globular bodies 76 per cent. Thrombocytes 800/c.mm. Erythroblasts 5/100 leukocytes. Reticulocytes 1.3 per cent. Coombs' test, macroglobulins, cryoglobulins, and cryofibrinogens were negative. Electrophoresis of serum proteins: Total proteins 5.18, albumin 1.53 (decreased), alpha_1 0.59 (increased), alpha_2 0.77, beta 0.94, gamma 1.36 grams per cent. Sternal marrow biopsy showed all marrow units affected by a malignant reticuloma of the lymphosarcoma type. Numerous neoplastic cells with one to many various sized intracytoplasmic PAS positive globular bodies were present. Her temperature ranged between 98 to 103 degrees. She received a total of 1600 ml. of whole blood, raising the hemoglobin to 13.4 grams per cent. She had a progressive downhill course and expired on April 16, 1964.

---

*Director Hematology Section, Department of Pathology and Clinical Laboratories, St. Barnabas Hospital.

Autopsy

Gross

The following is an abstract of the autopsy findings. Numerous petechiae were scattered about the entire skin and large ecchymotic areas were on the arms. The pleural cavities contained approximately 100 ml. of clear xanthochromic fluid. The pericardial sac contained 30 ml. of clear fluid. Weight of heart 350 grams. Right lung 600 grams, left lung 450 grams. Soft white tumor nodules were scattered about the lungs and most prominent in the lower lobes. The largest nodule measured 3 cm. The lymph nodes of the hilum showed marked tumor involvement. Weight of the spleen 300 grams. The cut surface revealed dark areas of infarctions. Weight of the liver with the gallbladder attached 1500 grams. Grossly no evidence of tumor. Adrenals and the pancreas were free of tumor. Weight of kidneys 150 grams each. They were free of tumor. Atrophic uterus and ovaries. Generalized adenopathy. The head and neck organs were not examined.

The stomach showed involvement by tumor grossly consistent with malignant lymphoma. A large area of ulceration was present. The small and large bowel showed several various sized tumor masses involving the mucosa and muscle walls. In the mid-portion of the jejunum was a 4 to 5-cm. area containing tumor and in the central portion a large perforation of the bowel 2 cm. in diameter. This segment of bowel was attached to another portion of bowel and mesentery producing a self-sealing process. The mesentery was markedly involved with tumor.

Microscopic

Sections show the presence of malignant reticuloma of the lymphosarcoma type involving the stomach, lungs, liver, spleen, small bowel, lymph nodes, mesentery, bone marrow, and the peripheral blood. Many neoplastic cells contain periodic acid Schiff (PAS) positive globular bodies.

Final Autopsy Diagnosis

1. Malignant reticuloma-lymphosarcoma
2. Perforation of the jejunum due to tumor
3. Bilateral hydrothorax
4. Acute splenic infarction
5. Old subtotal gastrectomy for probable lymphosarcoma

Cytochemical Studies of the Globular Bodies

Air-dried peripheral blood films and marrow smears were stained with Wright's Blood Stain buffered with deionized water pH 5.5. The intracytoplasmic globular bodies were achromatic to this staining procedure. When a diluent pH 6.5 was used the greater number of the globules stained faintly eosinophilic with a more or less distinct bluish rim surrounding the bodies. Figure 1 on the cover of this journal shows the morphology of the intracytoplasmic globular bodies in neoplastic lymphoid cells present in the peripheral blood. When the stain was buffered with a diluent pH 7.2 the bodies showed an affinity to the methylene azure components of the Wright's Blood Stain. The rim surrounding the globules also was more chromatic. Figure 4 on the cover of this journal is a lymph node imprint showing the chromatic character of the bodies and rim.

Hematoxylin-Eosin Staining Reaction of the Globular Bodies

Air-dried peripheral blood films, marrow smears, and imprints of tumor tissue were fixed in formalin vapor for five minutes, washed in deionized water, and stained with hematoxylin-eosin. The globules revealed a strong affinity for eosin.

Unna-Pappenheim Staining Reaction of the Globular Bodies

Another set of formalin vapor fixed smears and imprints were exposed to the Unna-Pappenheim stain for 15 minutes, then rinsed in deionized water and differentiated in acetone. The bodies showed various degrees of affinity for the pyronin dye suggesting the presence of ribonucleic acid in the globules. The rim about the bodies stained faintly reddish-purple.

Periodic Acid Schiff (PAS) Staining Reaction of the Globular Bodies

Air-dried peripheral blood films, marrow smears, and tumor tissue imprints were exposed to formalin vapor for five minutes; rinsed in deionized water; placed in potassium metaperiodate-nitric acid solution for five minutes; rinsed well in several changes of deionized water; exposed to the Schiff reagent for 15 minutes; transferred into dilute sodium metabisulfite solution (10 per cent) 6 ml. to 120 ml. deionized water, three changes two minutes each; rinsed well in deionized water; slightly counterstained with Harris hematoxylin; differentiated in phosphotungstic acid solution (2 per cent); rinsed in deionized water and placed into dilute ammonium water till the preparations turned blue; washed in deionized water and the preparations allowed to air dry. The same staining procedure was applied to marrow and tumor tissue previously fixed in neutral formalin-saline fluid.

Result

The globular bodies showed various degrees of PAS positiveness ranging from very light to deep red. The rim of the globules stained various shades of bluish-red. Figure 2 (peripheral blood), Figure 3 (lymph node imprint), and Figure 5 (section of tumor) on the cover of this journal show the tinctorial reactions of the cytoplasm, globules, and the rim. The different affinities to the PAS reagent of the cytoplasm and the globules may be attributed to a fluctuating concentration of polysaccharides. In general, the cytoplasm is less fuchsinophilic than the bodies, suggesting that the greater amount of PAS positive material is incorporated into the globules. Near the center and upper border of the section of tumor shown in Figure 5 is a neoplastic cell with three giant laminated PAS positive bodies. Whether they are made up of superimposed globules, disclike crystallization of a giant Russell body, or are the result of coalescence of numerous minute globules is not known. The presence of PAS positive globules in histiocytes is noteworthy, suggesting that free bodies are phagocyted. It is conceivable that cells containing bodies that have none or a very weak PAS positiveness may be mistaken for "morular cells of Mott" or "grape cells," although according to Zlotnick[5] these cells are plasmocytes (plasma cells) and generally associated with hypergammaglobulinemia. Since the bodies of the morular and grape cells are invariably PAS negative, erroneous identification of these cells is not likely. It is noteworthy that Russell bodies were present in neoplastic cells undergoing mitosis.

In addition to our cytochemical studies, the staining methods of Pearse,[6] Rappaport and Johnson,[2] and saliva digestion method in conjunction with the PAS reagent were applied to the intracytoplasmic globular bodies. Analysis of our over-all results showed a good correlation with those recorded in the literature. Thus it seemed reasonable to consider the globular bodies in the neoplastic cells in our preparations true Russell bodies, particularly since the bodies were cytochemically identical to the Russell bodies in lymphocytes, plasma cells, and multiple myeloma cells. Whether the rim surrounding the bodies is made up of ribonucleic acid only, as assumed by Pearse, could not be established. That the rim (Russell's delicate cementing substance) is compressed cytoplasmic ribonucleoprotein is more likely.

Russell Bodies and Theories of Origin

Pearse[6] states that "Dr. William Russell in 1890 described intracytoplasmic acidophilic bodies in small round cells at the margin of various malignant growths. He thought them to be fungi and characteristic of organisms of cancer. Russell noted that globule clusters of two to twenty and more were present in the cells, and that the larger aggregates were held together by a 'delicate cementing substance' which stained faintly. For the demonstration of the bodies he used eosin, carbol fuchsin, and iodine green."

Russell Bodies in Plasma Cells

Cells containing Russell bodies were noted by Jordan[7] in the spleen and lymph nodes of the guinea pig and rabbit. According to Jordan the "Russell body cell" arises from the lymphocyte. An intermediate stage of lymphocyte transformation is the plasma cell. He states that the "Russell fuchsin bodies exist in form of spheroidal globules, granules, and crystalloids. They are homogeneous structures with an oxyphilic staining reaction of variable degree, elaborated within the cytoplasm, apparently as the result of some regressive change. Russell body cells apparently represent late stages in a degenerative process." In the Ophthalmic Pathology an Atlas and Textbook, edited by Friedenwald,[8] the following opinion is presented: "A degenerative change of the plasma cell is the plasmacytoid cell. The cytoplasm is no longer homogeneous and basophilic but filled with acidophilic granules. They coalesce and form rosettes around a pyknotic nucleus. These and subsequent forms are known as Russell bodies. The coalescence of the hyaline globular material appears to continue, forming raspberry-like structures, and later large homogeneous masses, usually round (disc-like in microscopic sections) but are occasionally rectangular. They are set free in the tissue."

Pearse[6] is credited with being the first investigator presenting a plausible hypothesis of the development of the Russell bodies in plasma cells. According to Pearse the process is as follows: The faintly Schiff positive plasma cell, generally normal in size, enlarges and becomes increasingly more positive. The material becomes finely granular, associated with a decrease of the staining intensity of the cytoplasm. The granules gradually enlarge and become globular, reaching the size of an erythrocyte or larger. The intensity of staining rises simultaneously. The cell may become so full of globules and the color of the same so deep red that they appear to coalesce. Each body is surrounded by a delicate cementing substance consisting of ribonucleic acid. The bodies failed to bind methylene blue at pH 6. Thus he assumed that the globules were devoid of metachromatic properties. Pearse concluded that "Russell bodies consist of mucoproteins surrounded by ribonucleic acid." He presumed that the mucoproteins are polysaccharides containing globulins (glycoglobulins-mucoglobulins) secreted by the cell.

Hanoaka[9] investigated the origin of Russell bodies in plasma cells employing the supravital technique and the phase contrast microscope. He is of the opinion that the bodies are of mitochondrial origin. Hanoaka advocates that protein synthesis occurs in these constituents of the cytoplasm and that normally the mitochondria are short rod-like or thread-like in shape and under intense irritation enlarge due to acceleration of protein synthesis. The mitochondria become rosary-like and after splitting develop into globules, some progressing to large drops-Russell bodies. Braunsteiner,[10] Braunsteiner and Pakesch[11] observed with the aid of the electron microscope lamellar structures in the cytoplasm of plasma cells. They advance the opinion that the lamellae are protein producing structures. A direct transformation of the lamellae into secretion droplets was observed by these investigators. Lymphoblasts and lymphocytes had no such comparable structures.

Russell Bodies in Lymphocytes

Wislocki et al.[12] found that normal and leukemic lymphocytes contained PAS positive cytoplasmic granules. Rappaport[1] studied patients with acquired hemolytic anemia associated with either chronic lymphocytic leukemia or lymphosarcoma. He noted in neoplastic lymphocytes intracytoplasmic bodies with a strong PAS reaction resembling Russell bodies. Rappaport suggested that the bodies were produced by the cell and that they are comparable with those in plasma cells and multiple myeloma cells. He found neoplastic cells containing PAS positive globules in lymph nodes, spleen, bone marrow, and in reticuloendothelial cells filling the lymph node sinuses. Rappaport saw no plasma cells with PAS positive bodies. Mitus et al.[3] report a greatly increased glycogen content of lymphocytes of lymphatic leukemia and lymphosarcoma. No reference to Russell bodies is made by these investigators. Quaglino and Hayhoe[4] also found a high PAS positive score in lymphosarcoma cells. The positiveness being expressed either in "concentric annular rings of granules or large clumps" in the cytoplasm. The strongest positivity was in patients with widespread disease.

Rappaport and Johnson[2] noted in neoplastic lymphocytes of three cases of malignant lymphoma a single large intracytoplasmic acidophilic inclusion body that had morphologic, tinctorial, and cytochemical properties of Russell bodies. They state that "usually a single globule occupied almost the entire cell body, pushing the nucleus to the periphery. The globules did not have the basophilic peripheral rim, were not as round and as sharply defined as typical Russell bodies of plasma cells." Thus Rappaport and Johnson refer to the globules as "Russell body-like intracytoplasmic acidophilic material." They further observed that the globules lost none of the staining intensity after diastase treatment and that the material was negative for acid mucopolysaccharides. These investigators concluded that "the Russell body-like material is formed by the neoplastic lymphocytes in which it is contained and that the material may represent an abnormal protein (globulin)."

Electron Microscopic Studies of Russell Bodies

Welsh[13] made a comparative study of Russell bodies in plasma cells employing the light and electron microscope. He found that the PAS positive cytoplasmic bodies were in intracisternal spaces and always bounded by a membrane of endoplasmic reticulum.

Isoelectric Point and Size Range of Russell Bodies

Goldberg and Deane[14] found that the isoelectric point of Russell bodies ranged from pH 6.2 to 7.5, reflecting the variation of the isoelectric points of gamma globulins present in the bodies. Thus if the applied stain is on the alkaline side of the isoelectric point of a Russell body the latter stains basophilic (bluish), near the isoelectric point (amphoteric) violet to purple, and when on the acid site the body stains acidophilic (pink to red).

Bangle[15] studied Russell bodies in frozen sections and found them to be colorless. The bodies ranged in size from 0.5 to 30 micra but generally ranged between 2 to 15 micra.

Discussion and Summary

The extensive publications, some of which are cited pertaining to the origin and chemical nature of Russell bodies, correlated with our morphologic-histochemical studies of Russell bodies, suggests a logical sequence of their development.

Normally protein is synthesized by the mitochondria and probably concomitantly a protein-polysaccharide complex is produced. This material is apparently not homogeneous and thus fails to stain or is only faintly PAS positive. At this formative stage the cytoplasm displays a distinct pyroninophilia resulting from the presence of ribonucleoprotein. The PAS positiveness increases with the formation of chondriospheres.* It does not follow that all spheres have a sufficient quantity of polysaccharides to give a positive PAS reaction. As the globules transform into Russell bodies they tend to become more homogeneous. The size and degree of color intensity of the bodies to eosin, pyronin and the PAS reagent seem to be directly proportional to the quantity and quality of ribonucleoprotein, glycoprotein, glycogen, and possibly as yet unknown PAS positive and negative substances present in the individual Russell body. Thus it can be reasoned that when the intracytoplasmic metabolism becomes increasingly uncontrolled morphologic and cytochemical variations of Russell bodies are to be anticipated. On the basis of this supposition it seems justifiable to consider the single large "Russell body-like globule" of Rappaport and Johnson an aberrant form of Russell bodies. This interpretation is supported by the presence of identical globules in our preparations.

It is our opinion that Russell bodies in lymphocytes, plasma cells, and multiple myeloma cells are the result of a greatly accelerated cytoplasmic activity, and giant Russell bodies are the product of a completely disrupted intracytoplasmic metabolic process.

The presence of free Russell bodies in the peripheral blood films, marrow smears, and tumor tissues is likely the result of cell death and or rupture of neoplastic cells by the pressure exerted on the cytoplasm by the bodies. It is noteworthy that histiocytes tend to phagocyte Russell bodies, although their final disposition is unknown. Whether giant Russell bodies are bearers of a malignant stimulus awaits investigation.

*See Test Your Word Score Page 1167.

Summary

A case of leukemic lymphosarcomatosis with giant Russell bodies in neoplastic cells is presented. No comparable report was found in the literature. The formation of Russell bodies is discussed.

Acknowledgment

Thanks are extended to Dr. Frank B. Johnson, Armed Forces Institute of Pathology, Washington, D. C. for the loan of histologic preparations showing a "Russell body-like globule" in neoplastic lymphocytes; to Dr. Frank E. Martin for allowing this writer to study and report this unusual case; to Drs. N. H. Lufkin, W. A. Chadbourn, and J. G. Popowich, Department of Pathology, St. Barnabas Hospital for their cooperation and support of this research project.

Magic Numbers

Observance of number is a feature in Pliny's ceremonial; his recipes frequently recommend that the operation be thrice repeated. In the case of curing scrofula by the ashes of vipers he prescribes three fingers thereof taken in drink for thrice seven days. In another application of a Gallic herb with old axle-grease which has not touched iron, not only must the patient spit thrice to the right, but the remedy is more efficacious if three men representing three different nations anoint the right side with it. For a head-wash ten green lizards are boiled in ten sextarii* of oil, and for an application to prevent eyelashes from growing again when they have been pulled out fifteen frogs are impaled on fifteen bulrushes.**

Hemorrhagic Thrombocythemia as a Cause of Gastrointestinal Hemorrhage

JAMES MYHRE, M.D.*
Minneapolis, Minnesota

THE MOST common causes of gastrointestinal hemorrhage are peptic ulceration, esophageal varices, and carcinoma. However, many unusual and rare causes are also described. Hemorrhagic thrombocythemia** has not been included in most considerations of this problem but should be regarded as a diagnostic possibility, though a rare one. This clinical syndrome is a paradox of recurrent bleeding, commonly gastrointestinal, associated with very high platelet counts and frequently with thrombotic phenomena.

Case Report

A fifty-eight-year-old female was seen on December 1, 1962, complaining of three weeks of shortness of breath.

History

The systemic inquiry revealed chronic headaches, chronic constipation without any evidence of red blood or black stools, and usually one episode of nocturia with occasional stress incontinence.

The past medical history revealed a hysterectomy, urinary bladder suspension surgery, anal fissurectomy, and four hospitalizations for acute diverticulitis occurring within the previous nine years. Additional medical diagnoses were chronic anxiety, overweight, myositis of the trapezius and, in 1957, a gastrointestinal hemorrhage with the x-ray findings of a sliding hiatus hernia and a duodenal deformity.

Examination

Examination revealed a weight of 141 pounds and a height of 61 inches. Positive physical findings were pallor, moderate enlargement of submaxillary nodes unchanged for five years, an inconstant grade I and II apical systolic murmur, normal blood pressure, and an obese abdomen.

Laboratory Findings

There were 8.1 grams per cent of hemoglobin with 10,000 W.B.C.s per c.mm. with 62 per cent neutrophiles, 32 per cent lymphocytes, 2 per cent monocytes, 2 per cent eosinophiles, and 2 per cent basophiles with anisocytosis, hypochromasia, and an increased number of platelets in the peripheral blood smear. The initial reticulocyte count was 2.7 per cent; on intramuscular iron therapy it rose to 4.3. The platelet counts were 3.7 million and 3.87 million per c.mm. (Reed and Ecker method with normal values of .2 to .35 million per c.mm.). The blood sugar was 103 milligrams per cent. The serum bilirubin was 0 at one minute and 0.06 milligrams per cent total. There were 6.1 grams per cent total protein with 3.9 grams per cent of albumin and 2.2 grams per cent of globulin. The patient's prothrombin time was 17.2 with a control of 14.1 seconds. The L. E. clot test was negative. The stools were 4 plus with benzidine dihydrochloride testing. The latex test for L. E. cells was negative, as was the urinalysis. The fecal urobilinogen was 40.2 Ehrlich units per 100 grams of feces.

*Clinical Assistant Professor of Medicine, University of Minnesota Medical School and Northwestern Hospital.

**See Test Your Word Score Page 1167.

The *bone marrow sections* revealed an increased number of megakaryocytes and platelets. The myeloid-erythroid layer was 2 per cent with the megakaryocytic layer being 12 per cent. There were 0 per cent myeloblasts, 3.8 per cent promyelocytes, 10.2 per cent myelocytes, 15.2 per cent metamyelocytes in the neutrophilic group, 0.4 per cent metamyelocytes in the eosinophilic group, 0 per cent mature eosinophiles, 20.8 per cent mature neutrophiles, 0.8 per cent mature basophiles, 8.2 per cent lymphocytes and 32.6 per cent normoblasts. The developing red cells were normoblastic and there was no evidence of leukemia. The electrophoretic pattern revealed 4.0 grams per cent of albumin, alpha 1 globulin 0.2 grams per cent, alpha 2 globulin 0.7 grams per cent, beta globulin 0.7 grams per cent and gamma globulin 0.5 grams per cent.

The chest X ray and electrocardiogram were normal. The stomach X ray revealed a hiatus hernia and a crater in a deformed bulb.

Treatment and Prognosis

The patient was treated with intramuscular iron, hourly milk and antacids, elevation of the head of the bed, phenobarbital, rest and a progressive Sippy diet. She was discharged in eighteen days with a hemoglobin of 9.7 grams per cent and the stools negative when tested with benzidine dihydrochloride.

Recurrent Symptoms

She was readmitted on February 8, 1963, because of two days of multiple black stools. She had been noticing lower abdominal crampy distress but no upper abdominal distress. She felt a bit warm and moist but had not fainted. The admission hemoglobin was 9.1 grams per cent with a hematocrit of 28 and a platelet count of 2.12 million per c.mm. The same medical regime enumerated above was restarted at this time. The string test suggested upper gastrointestinal bleeding. In grams per cent the blood calcium was 10.3, the phosphorus 4.6 and the uric acid 6.9. Later there were 2.7 million platelets per c.mm. with a prothrombin time of 17.5 seconds with a control of 14.9. Ivy bleeding time was 16 minutes.

By the end of February, 1963, there were 2.6 million platelets with 10.7 grams per cent of hemoglobin and a normal white blood count and differential with many atypical appearing platelets in a peripheral smear. At that time the Lee-White coagulation time was eight minutes, the Ivy bleeding time in excess of 96 minutes, and the Duke bleeding time 40 minutes. The qualitative fibrinogen was normal, with beginning clot retraction at seven seconds and a firm clot with a moderate amount of fluid extruded at 60 minutes. A transfusion of 500 cc. of whole blood was given in an attempt to improve hemostasis, but only one unit of blood was used because of an inability to obtain cross matching due to an anti-Duffy factor.

Additional Observations

The X-ray examination of the esophagus revealed a small sliding hiatus hernia with gastroesophageal reflux, tertiary contractions, and a small pinpoint area with radiating folds suggesting a minimal crater in the hiatus-herniated portion of the stomach. There was also a mild deformity of the superior portion of the duodenal cap, and radiating mucosal folds were visible here as well to suggest ulceration. The X-ray examination of the colon revealed multiple diverticula, especially in the lower descending colon and sigmoid area with irregular margins suggesting some old diverticulitis. A few small diverticula were present in the terminal ileum. She was discharged on a Sippy regime, feeling quite well.

The patient was readmitted on May 2, 1963, complaining again of black stools. At that time the physical examination showed no change except for pallor. Blood studies on admission revealed a hemoglobin of 10.6 grams per cent with a hematocrit of 30; 8,950 W.B.C.s per c.mm., 84 per cent neutrophiles, 11 per cent lymphocytes, 4 per cent monocytes, 1 per cent eosinophiles with one normoblast per 100 W.B.C.s, increased numbers of platelets in the peripheral smear including many atypical forms and basophilic stippling in the red blood cells. There were 1.52 million platelets per c.mm. By May 8, 1963, the platelet count was 1.6 million per c.mm., the prothrombin time was 15.0 seconds with a 14.4-second control. The Lee-White clotting time was nine minutes 30 seconds. The prothrombin consumption test was 54.1 seconds. In one-half hour a clot retraction was complete. She was discharged on a Sippy regime.

Radioactive Phosphorus Treatment

On May 21, 1963, four mc. of P-32 were given orally. Platelet counts came down in two to three weeks as seen in Table 1. Three mc. of P-32 were given on January 7, 1964, and a further drop in platelet counts in four to five weeks was noted.

On May 31, 1964, melena was noted with a decrease in hemoglobin concentration to 12.6 grams per cent with 1.6 million platelets per c.mm., Lee-White coagulation time of 12 minutes, normal prothrombin time, and a prothrombin consumption test of 40 minutes. She was given four mc. of P-32 intravenously and discharged with brown stools testing three plus with benzidine dihydrochloride.

Discussion

There have been two review articles published about this syndrome, which is of unknown etiology.[1,2] The most common symptom has been bleeding, and in the approximately sixty cases reported, as well as in occasional reports since, the gastrointestinal tract has been the common site of blood loss.

TABLE I

Date	Hemoglobin Grams Percent	Platelets Million Per c.mm.	
1 Dec. '62	8.1	3.87	
15 Jan. '63		2.6	
8 February	9.1	2.7	Normal prothrombin time. Ivy bleeding 16 minutes.
25 February		2.6	Lee-White 8 minutes. Ivy bleeding over 96 minutes. Duke bleeding 40 minutes.
2 May	10.6	1.6	Lee-White 9.5 minutes. Prothrombin consumption 54.1 minutes and good clot retraction.
21 May		2.16	Four mc. P-32 orally.
4 June	11.3	.78	
14 June	12.2	1.19	
21 June		1.31	
28 June		1.07	
9 July		1.09	
13 August		1.64	
12 September		1.98	
18 October	12.3	1.42	
20 November	13.0	1.14	Ivy bleeding 12 minutes. Lee-White clotting 20 minutes.
19 December		1.6	
7 Jan. '64			Three mc. P-32 orally.
30 January		1.2	
6 February		1.07	
20 February		.63	
13 March	14.4	.91	
15 March		1.3	
31 May		1.6	Lee-White time 12 minutes. Prothrombin consumption 40 sec.
6 June '64			Four mc. P-32 intravenously.

Laboratory values in patient with hemorrhagic thrombocythemia including treatment three times with P-32.

Peptic ulceration was demonstrated in eight of fifty cases and suspected in several others without confirmation. Ozer et al.[2] reported six cases, all but one of which experienced gastrointestinal bleeding. Only one patient, however, had a history compatible with peptic ulcer. In one instance, recurrent gastrointestinal bleeding recurred over a twenty-seven-year period.

The sex incidence appears to be evenly divided among males and females. The entity occurs most commonly in the middle and older age groups. Less frequent than gastrointestinal bleeding is hemoptysis, hematuria, menorrhagia and excessive bleeding after minor trauma, dental extractions, or operations. Spontaneous bruising often occurs; at times extremely large hematomata are formed after insignificant trauma. Purpura is not seen. Major bleeding occurs after splenectomy; therefore, this surgical procedure should be avoided. Approximately one third develop thromboses which occur in arteries or superficial and deep veins, especially the splenic vein. Priapism has been reported repeatedly.

The platelet counts were increased in all cases and varied according to the methods used. Counts ranged from 0.9 to 14 million per c.mm. with an average of around three million. The platelet morphology was often abnormal with many irregular and distorted shapes, giant forms and chains.

Bone-marrow examination generally has revealed a marked increase in megakaryocytes. The bleeding time has been exceedingly variable. Coagulation time is generally normal, as is the prothrombin consumption test and clot retraction.

Radioactive phosphorus has been found to be effective in treating this disorder in a manner similar to its use in polycythemia vera. As the platelet count falls, the hemorrhages diminish and eventually cease. Judicious repetition of the same or reduced doses of the isotope can maintain a normal platelet level and a good clinical state for long periods. Urethane, X-ray therapy and busulfan[3,4] have also been employed with success.

Summary and Conclusion

Gastrointestinal bleeding occurs commonly in an unusual clinical syndrome called hemorrhagic thrombocythemia, in which hemorrhage is paradoxically associated with an elevated platelet count and frequently with thrombotic phenomena. In this illustrative instance, three episodes of gastrointestinal bleeding were associated with platelet counts up to 3.87 million per c.mm. and an Ivy bleeding time which was in excess of 96 minutes on one occasion. The patient's peripheral blood smear had a marked increase in platelets eight years previously and there was a history of gastrointestinal bleeding five years previously. The primary source of the bleeding could have originated from the questionable crater in a hiatus hernia or from the chronic colonic diverticulitis, though more likely from the deformed duodenal bulb where a crater had been occasionally demonstrated.

P-32 therapy reduced the platelet count. It should be noted that the level of platelet count and bleeding did not always correlate. Also the platelet count and bleeding tendency spontaneously improved in this instance before P-32 therapy.

A platelet count is suggested as a pertinent part of the diagnostic work-up of any patient with gastrointestinal bleeding, as much for the possibility of thrombocytopenia, as well as for the more rare thrombocythemia. Apart from the high platelet count, there does not appear to be any consistent pattern of abnormality in hemostasis or coagulation in this apparently myeloproliferative syndrome of unknown etiology.

Mediastinoscopy

A Diagnostic Tool*

ARNDT J. DUVALL III, M.D.**
SEVERIN H. KOOP, JR., M.D.**
Minneapolis, Minnesota

THE INCREASING incidence of lung pathology has directed physicians to a number of different diagnostic modalities that can be utilized to determine the exact pathology. These modalities range from simple chest auscultation and percussion to exploratory thoracotomy. Between these, examination of the lung fields can be furthered with chest roentgenogram, bronchoscopy and bronchography, and the scalene node biopsy. This paper is concerned with the diagnostic procedure of mediastinoscopy — a method of examining the anterior mediastinum that is popular in northern Europe.

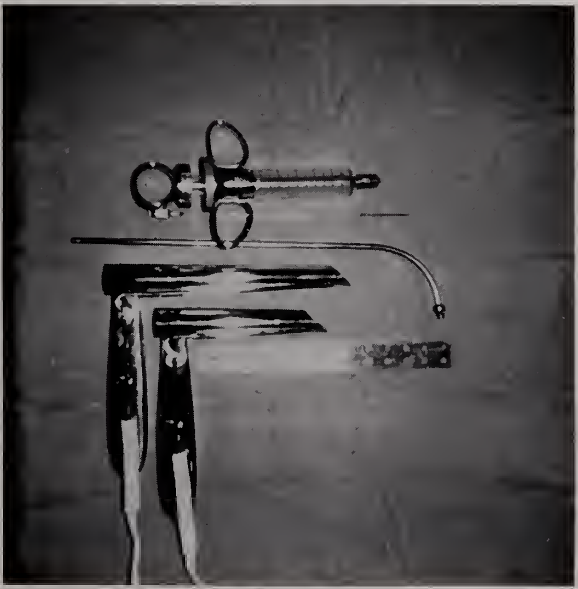

Fig. 1

The function of mediastinoscopy is akin to that of scalene node biopsy in that it attempts to ascertain the diagnosis or extent of pathology without resorting to exploratory thoracotomy. In 1949 Daniels proposed the scalene node biopsy for determining extrathoracic spread of lung malignancy and for establishing the diagnosis in certain nonmalignant cases.[1] The frequency of false negative results has led some to question the efficacy of the scalene node biopsy, especially in lung cancer.[2] In 1954 Harken suggested the use of bilateral cervical mediastinal exploration under local anesthesia with bilateral insertion of the laryngoscope.[3] This procedure is distressing to the patient and unsafe. Radner must be first credited (1955) with recommending biopsy of the paratracheal nodes through a suprasternal incision.[4] However, it was Carlens who put the procedure of mediastinoscopy on a practical basis.[5] One of us was fortunate to be able to work with Carlens in Stockholm.

---

*Presented at the Minnesota Academy of Ophthalmology and Otolaryngology, December 12, 1964.

**Department of Otolaryngology, University of Minnesota, Medical School.

Purpose

The procedure of mediastinoscopy has two purposes:

1. To examine the anterior mediastinum and obtain mediastinal biopsies for differential diagnostic purposes when a diagnosis has not been established by more conservative routine methods.

Palva,[6] in discussing the value of mediastinoscopy in the differential diagnosis of anterior mediastinal masses, describes how sarcoidosis can be discerned macroscopically because of the violet-colored, loose proliferating tissue masses found in the mediastinum in the earlier stages. As the condition advances to a more fibrotic form, the glands appear gray and are stony hard. The same stony-hard grayish glands also appear in cases of silicosis of long standing. In addition to obtaining the diagnosis in these diseases, Palva has also utilized mediastinoscopy in diagnosing vascular anomalies, mediastinal cysts and tuberculosis. Koskinen and Linden[7] stress that mediastinoscopy is perhaps most valuable in assessing nonmalignant lesions of the mediastinum.

2. As a means of determining resectability of proven cases of lung cancer by direct palpation, visualization, and biopsy of the anterior and lateral surfaces of the trachea, proximal main bronchi and surrounding structures.

The literature reveals that with present methods, 35-40% of patients subjected to thoracotomy with a diagnosis of lung carcinoma are found to be unresectable at the time of surgery, for even a negative scalene node biopsy does not preclude mediastinal involvement.[8] Reynders, in his institution, raised the resection rate for pulmonary cancer for 60% before mediastinoscopy to 94% after mediastinoscopy.[9]

Technique

General intubation anesthesia is used to prevent coughing during the procedure. A transverse incision is made in the suprasternal area and carried down to the anterior surface of the trachea, just as is done in performing a tracheotomy. This approach avoids danger to the large vessels in the neck, to the thoracic duct, and the apical pleura. It is now important that the very last layer of pretracheal fascia be incised. Once under this layer of fascia, finger dissection is carried out on the anterior surface of the trachea. The innominate artery and the aorta are anterior to the dissecting finger. Overzealous dissection could injure the recurrent laryngeal nerve on the left or the azygous vein on the right. After completion of the finger dissection, the mediastinoscope (Figure 1) is inserted under the pretracheal fascia, and the dissection is extended under direct vision with a velvet eye suction tip. Any suspicious tissue may be biopsied with a small laryngeal or bronchial biopsy forceps, but only after the tissue has been examined for vascularity. This is performed by inserting a long spinal needle through the mediastinoscope into the suspected tissue and aspirating. After biopsy, our experience has shown that any bleeding is minimal and easily controlled with a small gelfoam pledglet. After removal of the mediastinoscope, the subcutaneous tissue and skin are closed in a routine manner. Our series of cases has produced no complications, and this is in keeping with larger series reported from northern Europe.[6,8] Postoperative morbidity is practically nil. The patients are up and about and ready for discharge the morning after surgery.

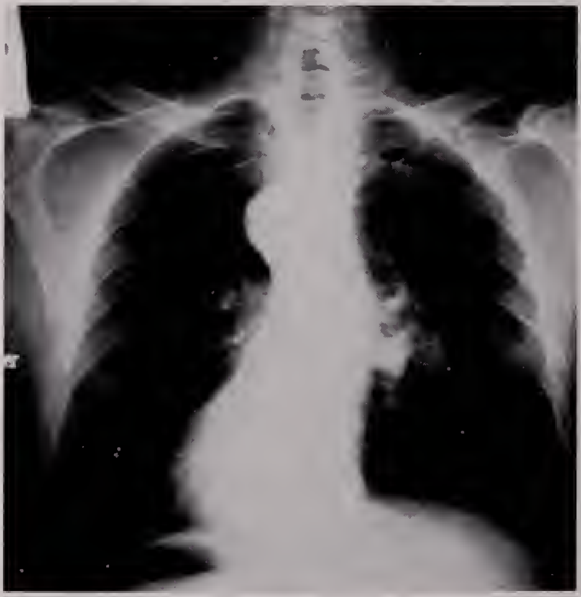

Fig. 2 — *Ed Note: In reverse — excuse.*

Case Report

A 79-year-old white male was admitted to the University Hospitals for the first time on June 8, 1964, for management of a basal cell carcinoma of the nose. Admission chest X ray (Figure 2) revealed an infiltrate in the anterior segment of the right upper lobe. Planigrams of the right hilum suggested a tumor mass. Bronchoscopy on June 15, 1964, was considered normal; however, two sputum examinations revealed cells suggestive of malignancy. In view of this finding, the patient received a course of X-ray therapy to the lung simultaneously with X-ray therapy to the nose lesion. On July 24, 1964, mediastinoscopy was performed under general anesthesia prior to the thoracotomy. Examination of the anterior mediastinum through the Carlens mediastinoscope revealed no abnormalities. The thoracotomy was then performed under the same general anesthesia, and the right upper lobe of the lung resected. The anterior mediastinum was free of any malignant nodes when examined at thoracotomy. The pathologist's report revealed squamous cell carcinoma of the right upper lobe.

Comment

Had the mediastinum been unresectably involved with malignancy, it would have been unfortunate to have subjected the patient to an exploratory thoracotomy.

Conclusions

This is a presentation of a procedure for examination of the anterior mediastinum for diagnosis of unknown masses and determination of extent of pathology. It is safe, with little morbidity. Mediastinoscopy might be beneficial in decreasing the necessity of exploratory thoracotomy in bronchiogenic carcinoma. We are presently evaluating the procedure's ability to eliminate unresectable cases without resorting to thoracotomy. No attempt has been made to tabulate the cases here, although it is planned to do so as the series enlarges. It is our aim in this article to publicize the procedure, technique and purpose so as to disseminate its utilization in this area.

Radioactive Isotope

VISUALIZATION OF radioisotopes localized in various parts of the body has become an important aspect of nuclear medicine. Radioisotopes of interest in this regard are those which are selectively taken up by certain organs and/or tissues of interest, and which emit radiations (usually gamma rays) detectable by a Geiger or scintillation counter. The differential isotopic uptake is usually viewed from a recording of the radioactivity as detected by a scintillation crystal as it scans the area of interest.

In most scanning situations, the uptake differential between target and nontarget tissues is relatively low. Thus maximum use must be made of the sensitivity and resolution of detector, analyzer and recorder systems in order to minimize the amount of administered radioactive material and still achieve meaningful information from the scan. The principles of focused collimation,[*] gamma ray spectrometry and photorecording are conventionally used.

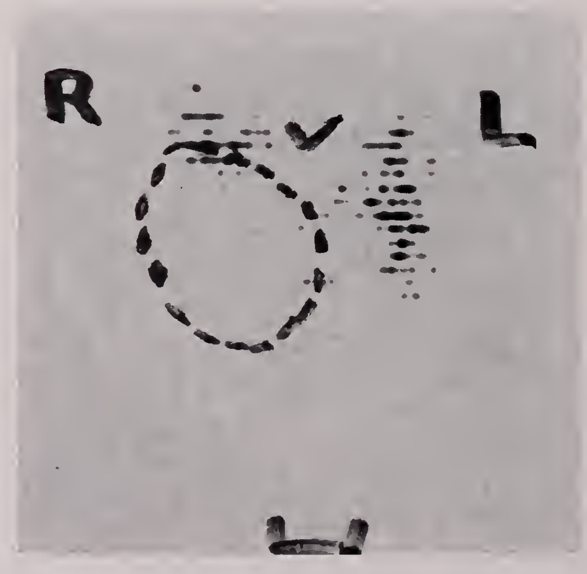

Fig. 1 — Thyroid scan using NaI^{131} showing a cold nodule.

A focused collimator permits a point-to-point relationship to be established between the area being scanned and its recording. The gamma ray spectrometer with its associated circuitry permits selective reception of electrical impulses produced by radiation coming from the target area, while discriminating against those impulses resulting from background radiation. By means of the photorecorder, the electrical impulses passing the spectrometer activate a light that moves in parallel with the detector. This light exposes x-ray film as it moves back and forth. The intensity of the light and consequently the blackening of the x-ray film is directly proportional to the radioactivity beneath the scintillation detector.

Scanning may be done to advantage with the differential uptake by the target tissues being either greater or less than by the surrounding nontarget tissues. Results are generally better when the uptake is greater in

the target tissues, since it is easier to detect a small volume of tissue with localized radioactivity than it is to find a volume of similar size that localizes radioactivity less well than surrounding tissues.

Thyroid

Due to a relatively high difference in radioiodine uptake between target and nontarget tissue, the thyroid lends itself particularly well to scanning techniques and was the first organ studied by this procedure.

Radioactive Iodine

Information as to size, shape and location of the thyroid may be gained from scanning following the oral administration of 50 microcuries of I-131 as sodium iodide. The results of thyroid scanning are also quite useful in deciding whether or not a palpable nodule in the thyroid is benign or malignant. Less than 10 per cent of malignant nodules concentrate iodine to any significant degree. A nodule within the thyroid which shows a greater activity in the surrounding tissue is almost certainly benign. A "cold" nodule, on the other hand, has much less diagnostic value because it may be malignant, or even more likely it may be an area of inactive or degenerated thyroid tissue or a thyroid cyst (Figures 1, 2, 3).

Liver

Isotope scanning is helpful in diagnosing liver disease, particularly in situations where the patient is suspected of having metastatic nodules in the liver.

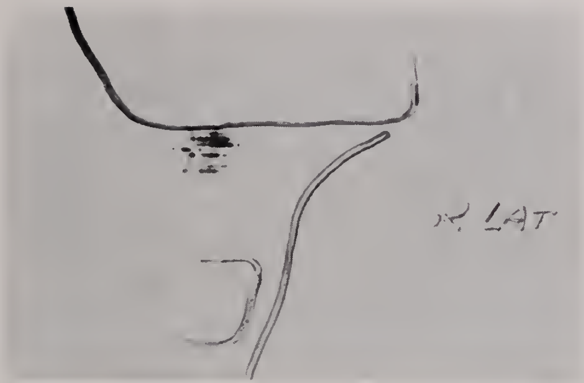

Fig. 2 — Right lateral scan of neck region with NaI^{131} showing sublingual thyroid. (Note lack of activity usual thyroid area).

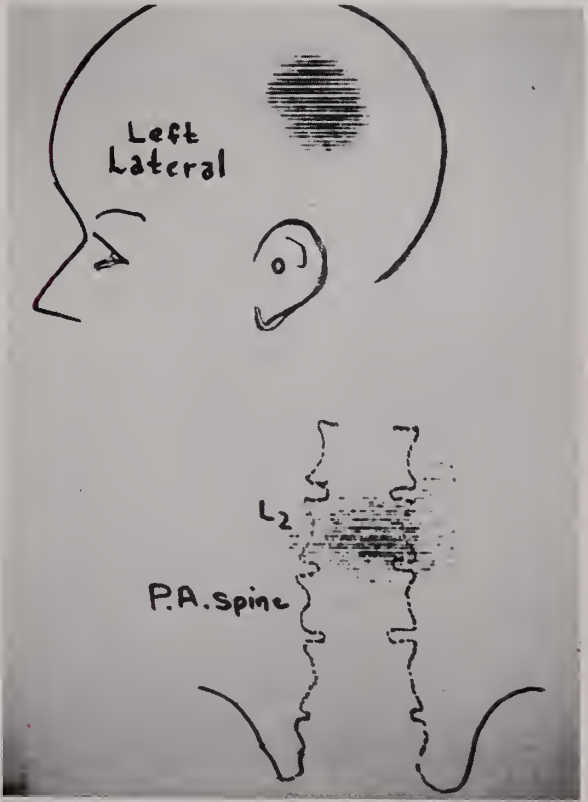

Fig. 3 — Scans with NaI^{131} over areas showing lytic lesions of bone in patient with proven follicular cell carcinoma of the thyroid.

Radioactive Gold

Three materials are being used in our laboratories for liver scanning. These are I-131 rose bengal, I-131 colloidal albumin, and colloidal gold Au-198. The rose bengal is picked up by the parenchymal cells of the liver and subsequently excreted into the duodenum with a clearance half-time of about two hours, although this varies from patient to patient depending upon the functional status of the liver. The colloidal albumin and colloidal gold particles are concentrated in the reticuloendothelial (Kupfer) cells of the liver. The colloidal albumin with a particle size of about 200 millimicrons clears fairly rapidly with a clearance half-time which may vary from one half hour to several hours, depending upon the amount of stable colloid which is administered simultaneously. The addition of 4 mg/kg. body weight of the stable colloid delays the excretion of the I-131 colloid albumin so that a uniform liver image may be produced in the time (approximately one hour) required for this procedure, using a conventional rectilinear scanning system. Colloid gold remains essentially fixed in the liver for the physical half-life of the isotope. Tumors, abscesses and cysts of the liver are not likely to take up any of these scanning materials and may thus be outlined as a negative shadow. Congenital or acquired malposition of the liver and certain abdominal masses may be identified by this scanning technique (Figure 4).

Spleen

Radioactive Sodium Chromate

The spleen may be visualized by a scanning technique using either Cr-51 tagged erythrocytes which have been damaged by heating or I-131 colloidal albumin. Because of the difficulties associated with the treatment of red cells, we have been using the I-131 colloidal albumin exclusively for spleen scans. Colloidal gold is of limited value for spleen scanning, since it is not taken up by the reticuloendothelial cells of the spleen as well as is the colloidal albumin. Recently Hg-203 or Hg-197 labeled Bromomercurihydroxypropane (BMHP) has been made available for spleen scanning. This material binds avidly to red cells, causing moderate damage of these cells so that they are sequestered by the spleen (Figure 5).

Brain

Major effort in scanning at this institution during the past three years has been directed toward the diagnosis of brain tumors. Initially, radioactive iodinated human serum albumin was used for this purpose and concentrated reasonably well in the more vascular brain tumors.

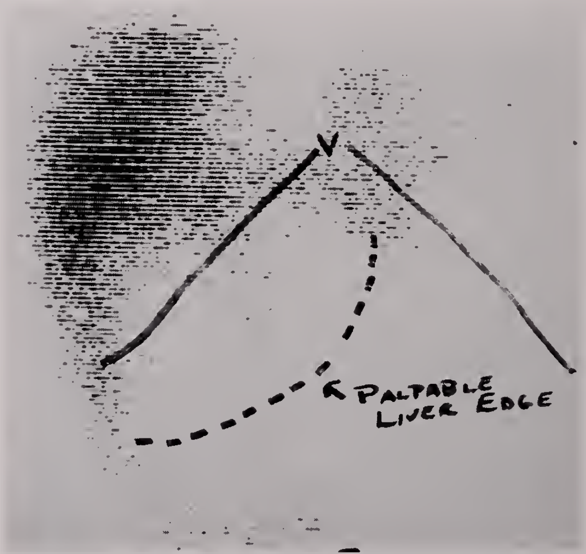

Fig. 4 — Liver scan using colloidal Au^{198} showing large filling defects due to hepatoma. This 18-year-old female also had previous cranial surgery for removal of a glioblastoma.

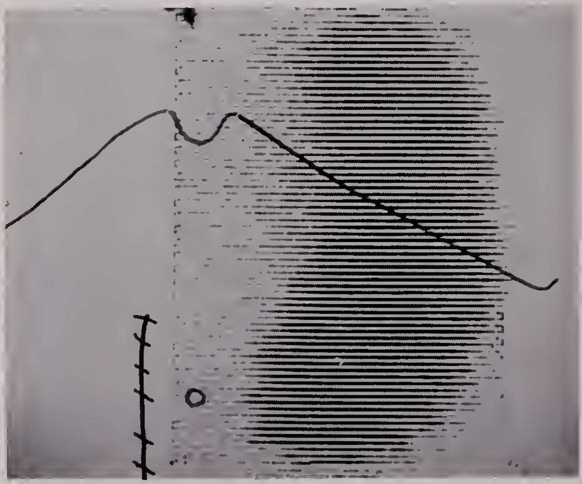

Fig. 5 — Abdominal scan with Hg^{197} mercurohydroxy propane showing marked splenomegaly in a patient with chronic leukemia.

Radioactive Mercury

During the past two years, we have been using Neohydrin tagged with Hg-203 or Hg-197 for brain scans. Our results indicate that scans with either of these agents will delineate brain tumors with about the same degree of accuracy available by angiography and pneumoencephalography We have achieved almost 100% success in detecting glioblastomas. Meningiomas and metastatic tumors have been localized with good success, using two orthogonal scanning planes. Likewise, cerebral abscesses and subdural hematomas have been detected. Relatively avasular tumors such as some astrocytomas are less well delineated. Our over-all success in localizing expanding lesions (both malignant and benign) is better than 85%. Occasionally this scanning method has demonstrated the presence of a brain tumor when other diagnostic techniques have failed and thus is a valuable screening procedure (Figure 6).

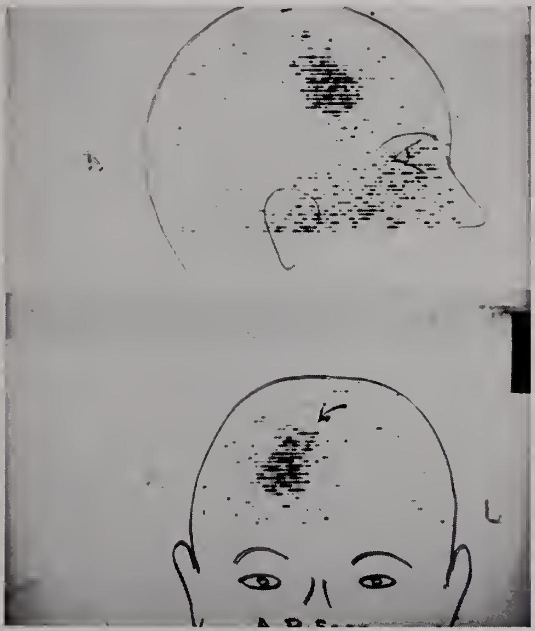

Fig. 6 — Hg^{197} Neohydrin brain scan showing increased activity in a well circumscribed glioblastoma.

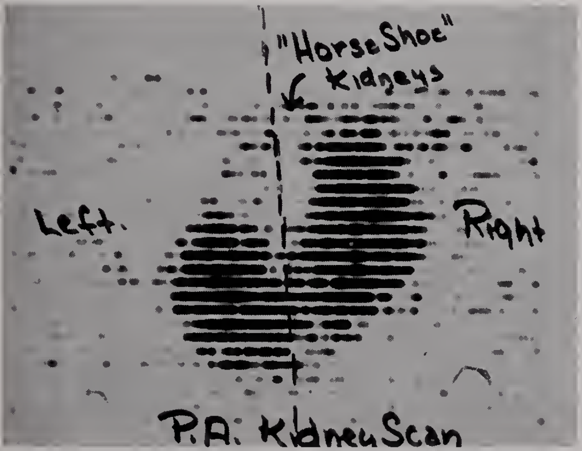

Fig. 7 — Hg^{203} Neohydrin kidney scan of a 3-year-old boy showing a typical horseshoe kidney.

Kidney

Radioactive Mercury-labeled Neohydrin

Scans of the kidneys may be obtained using Hg-197 or Hg-203 labeled Neohydrin. Neohydrin is taken up selectively by functioning kidneys so that kidney scans may be obtained, if desired, with all patients receiving this material for a brain scan. It follows from this that the radiation dose to kidneys constitutes a potential hazard in our technique of brain scanning. Kidney scanning permits exact localization of these organs and allows delineation of filling defects that may be associated with cysts or tumors of the kidney. In addition, a study of the rate and total uptake of Neohydrin by the kidneys yields information concerning renal function. In patients with poor renal function, there may be significant uptake of the Neohydrin by the liver, which may make the visualization of the right kidney particularly difficult because of its anatomic relation to the liver. Hippuric acid tagged with I-131 (Hippuran) has also been used for kidney scans; Hippuran is cleared rapidly from patients with good renal function and is therefore usually infused continuously during the scan (Figure 7).

Pancreas

Radioactive Selenium

We have achieved fair success in visualization of the pancreas, using selenomethionine in which the sulfur atom has been replaced by selenium-75 to provide the necessary gamma emissions. This technique is considered to be a useful adjunct to available diagnostic procedures for study of pancreatic disease. However, certain limitations are encountered which appear to restrict the diagnostic accuracy of the procedure in evaluation of pancreatic neoplasms. There are normal variations in the size and shape of the pancreas and also in the concentration of radioactivity in that organ despite controlled diet regimens instituted to selectively increase the uptake of selenomethione. Thus it is likely that small lesions located near the periphery of the pancreas will be missed. Selenomethionine is also taken up by the liver, which may obscure the pancreatic outline if there is enlargement or down displacement of the liver. Two other factors that should be considered are the relatively high cost of this isotopic preparation and its relatively long effective half-life in the body. The total body radiation dose to the patient receiving 3 microcuries of selenomethionine per kilogram body weight (the usual dose for a pancreas scan) has been estimated to be about 600 millirads. Pancreozynine, secretin, and high protein diet have been used to selectively increase the uptake of selenomethionine by the pancreas. Following the administration of the isotope, glutamic acid hydrochloride is sometimes administered to inhibit the pancreas and thus slow down the release of the radioactivity by this organ (Figure 8).

Bone

Radioactive Strontium

Bone lesions may be demonstrated by radioactive strontium. Two strontium isotopes, Sr-85 and Sr-87 M, have been used for this purpose. Sr-87 M has a rather short half-life of 2.8 hours, so that its application here is very limited. Our efforts have been directed to the use of Sr-85, which has a half-life of 65 days. The metabolism of strontium by bone is similar to that of calcium, although there are some differences in the handling of these elements by the kidneys and gastrointestinal tract. Usually 75 microcuries of Strontium-85 are administered intravenously and the patient is scanned 48 to 72 hours later. This allows up to 50% of the body's strontium content not deposited in bone to be excreted by the kidneys and bowel. It is known that satisfactory scans may be performed in 45 minutes after the injection because of the rapid uptake of this isotope by bone; but the rather high body background at this time makes scanning difficult. Because of the high excretion of Sr-85 by bowel, it is important that laxatives and enemas be used if one is interested in scanning the pelvis or lumbar spine. Sr-85 is taken up most readily by lesions which exhibit osteoblastic activity, although we have found significant uptake of this isotope in lesions which appear on x-

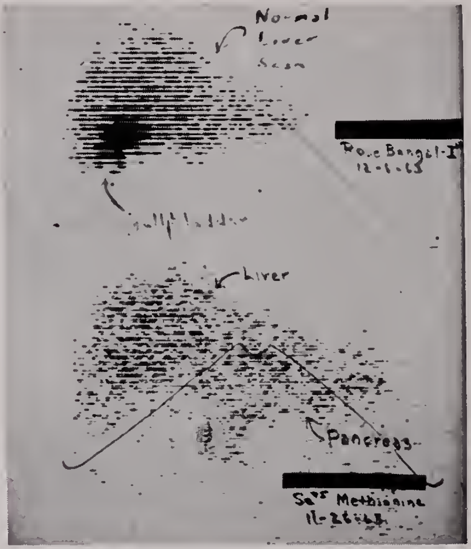

Fig. 8 — Upper scan of liver was performed with I^{131} Rose Bengal and shows filling of the gallbladder. Lower scan was performed subsequently on the same patient using Se^{75} Selenomethionine and shows liver and pancreas.

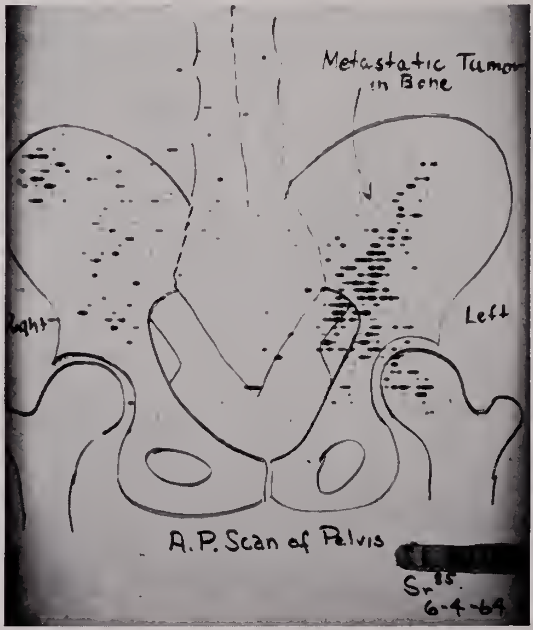

Fig. 9 — Bone scan using Sr^{85} showing lymphomatous involvement in left ilium.

ray films to be primarily osteolytic in character. We are now using this radioisotope for evaluation of patients with possible metastatic disease in bone where there is questionable roentgenographic evidence to support clinical evidence of such metastatic spread (Figure 9).

Lung

Radioactive Colloidal Albumin

Using colloid albumin with a mean particle size of 15 microns and tagged with I-131, we have begun a series of lung scans. This material is administered intravenously and, because of particle size, becomes trapped in the small arterioles and capillaries of the lung. The localization of the material is thus an indication of vascular supply. A dose of 2 microcuries per kilogram is normally administered. This constitutes a dose of 0.1 to 0.3 milligrams of colloid per kilogram of body weight, which then has a clearance half-time from the lungs of about five hours. Experiments with small animals indicate that toxic effects are not encountered below a dose almost 200 times greater than that used for patient studies. Results to date indicate that this procedure may serve as a very simple and useful method for early detection of pulmonary infarcts before any roentgenographic changes are evident. We are also performing the scans on patients with various other forms of pulmonary pathology, including cancer, pneumonia, and atelectasis (Figure 10).

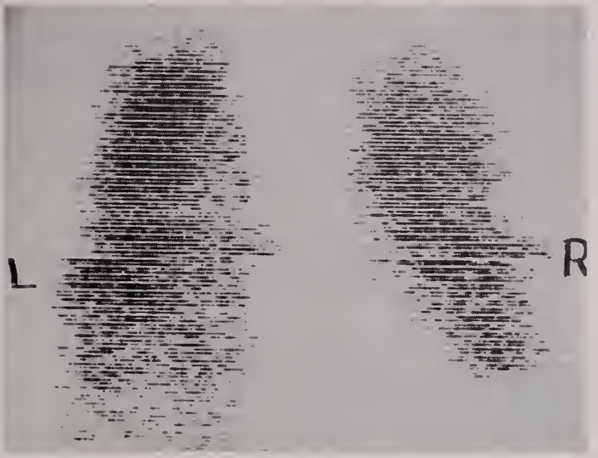

Fig. 10 — Posterior lung scan using macroaggregates of I^{131} albumin showing diminution in perfusion of both lower lobes suggesting pulmonary embolization. Chest x-ray at this time was unremarkable but a repeat radiograph several days later showed evidence of infarction, more marked in right lower lobe. Autopsy one week following lung scan confirmed the embolization and subsequent infarction.

Summary

The future of organ and tissue visualization by radioisotopic means holds much promise. The availability of isotope cameras and very short-lived isotopes will alter, in part, our present approach to isotopic visualization of organs. With these revisions it is possible to complete scans in a much shorter time. It will also be possible to study various dynamic processes such as cardiac, liver and renal function.

CAST SYNDROME

(Hyperextension of the Spine Syndrome)

This syndrome is characterized by dilatation of the stomach, adynamic ileus of the bowel, associated with severe pain in the abdomen and back. There may be persistent vomiting and an electrolyte imbalance may develop.

It usually occurs following the application of a plaster cast to the body.

Treatment consists of inserting a nasal gastric suction tube and a correction of the electrolyte imbalance. In some instances, it is necessary to remove the body cast.

Tracheoesophageal Fistula

S. HARTLEY CALIN, M.D.*
FRANK E. MORK, JR., M.D.*
Minneapolis Minnesota

THERE ARE two basic types of tracheoesophageal fistula: that associated with esophageal atresia, and the "H-type" fistula without atresia. The former offers no particular problem in roentgen diagnosis; the "H-type" fistula, on the other hand, is especially difficult to demonstrate roentgenographically. Many cases undoubtedly escape the attention of both the clinician and the radiologist. The purpose of this case report is to recommend the use of cineradiography for the detection of this anomaly.

Case Report

A 7 lb., 13 oz. white male infant was born following an uneventful pregnancy. One hour after delivery the infant experienced cyanosis and dyspnea which responded satisfactorily to suction. A chest film revealed no abnormality. The following day the same symptoms recurred during feeding. A nasogastric tube was successfully passed into the stomach, thereby confirming the absence of an esophageal atresia. The infant was subsequently brought to the Radiology Department for an esophagram. Conventional fluoroscopy was performed with the injection of aqueous Dionosil through a small rubber tube in the distal esophagus. The findings were not conclusive, but it was thought that a fistula did exist at the level of the carina. A repeat fluoroscopic examination with multiple spot films was done the following morning, and again the fistulous tract was thought to be present at the level of the carina. A thoracotomy was performed, but the surgeons failed to find any fistulous communication.

About one week following surgery symptoms of dyspnea and cyanosis reappeared after feedings. Upon the insistence of a pediatric resident who steadfastly considered the possibility of an unrecognized "H-type" fistula, the baby was again examined in the Radiology Department. Cinefluorography was performed on this occasion with particular attention directed to the pharynx and proximal esophagus. The film was exposed 30 frames per second. A definite fistulous tract between the esophagus and trachea was convincingly demonstrated at the level of the sixth cervical vertebra, several centimeters below the larynx (See Fig. 1). Interestingly, the fistula was never seen with the child in the resting state, but the communication was repeatedly visualized when the patient coughed or cried. Surgery was again performed, through a small vertical incision on the right side of the neck, and the small fistulous tract was exposed and excised. Postoperative recovery was uneventful. One year later the child was gaining weight and developing normally.

Comment

"H-type" tracheoesophageal fistulas are reportedly quite rare; they are said to account for only 3% of all the congenital tracheoesophageal malformations.[1] A recent review of the literature on the subject showed that over 70 cases have been reported.[2] These isolated tracheoesophageal communications have been found at all levels of the trachea from the second tracheal ring to the carina, with 20% of the reported cases occurring in the cervical area.[3] Of the total 13 cases reported where the fistula was found in the neck, only six have been successfully treated.[3]

Roentgen Diagnosis

The roentgen diagnosis of the "H-type"

---

*Department of Radiology, St. Barnabas Hospital.

tracheoesophageal fistula is difficult for a variety of reasons. Many of these problems can be minimized, however, by the routine use of cinefluoroscopy in infants with swallowing problems. First, the fistulous communication can be quite small, often measuring only a few millimeters in diameter. Second, the communication may be in the cervical region where the passage of contrast material may be quite rapid. Third, the fistulous tract may fill only at certain times during the examination. It is better seen when the patient is crying or coughing. Fourth, in the cervical area it can be very difficult to differentiate between aspiration and a fistula, especially in the early stages of life when there is often evidence of inco-ordination in the swallowing mechanism. X-ray examination is best carried out with the child in the lateral or left anterior oblique position. Dionosil is the contrast material of choice. It should be injected carefully through a small rubber tube initially in the lower and mid-esophagus and then in the cervical esophagus. Multiple spot films or preferably cineradiographic films should be obtained of the entire esophagus, with special attention directed to the cervical region if a fistula is not seen in the chest. Finally, in order to prevent the possibility of aspiration pneumonia, care should be taken not to flood the trachea with contrast medium.

Conclusion

A plea is made for the utilization of cinefluorography on any patient who is suspected of having an isolated tracheoesophageal fistula. It is hoped that with the wider use of cinefluorography in infants and children with respiratory or swallowing problems more of these potentially life-threating anomalies will be discovered.

IT'S THE LAW

An individual is considered to be under the influence of intoxicating liquor when the blood alcohol level is .15 per cent or more.

Arrest is not a prerequisite to the blood alcohol test when the driver has given consent,[1] and an officer is not required to tell the driver of all of his rights under the "blood test" statute.[2] The admission in evidence of a blood alcohol test is not reversible, especially when there is sufficient and overwhelming evidence of the driver's intoxication based on observation a short time after the occurrence of the accident.[3] Written consent is not required for admission of blood test results when the driver has given his oral consent to the test.[4]

The individual who refuses to submit to a blood test for intoxication, insisting that the test must be done by his personal physician can be judged intoxicated on the basis of the arresting officer's opinion[5] and a driver's license can be revoked under the implied consent law if he refuses to submit to a chemical test for intoxication when the arresting officer explains the consequences of his failure to submit to the test.[6]

Reflections of a Neuropsychiatrist in a Court of Justice

ROBERT P. JEUB, M.D.*
Minneapolis, Minnesota

MANY OF us have had occasion to appear as expert witnesses before a judicial tribunal and are very much aware of the degree of emotional reaction that directs the participants in a trial. Partisanship on behalf of the defendant or the prosecution plays a continuous role. The law expects medical opinion as to whether or not the defendant is mentally ill and whether or not there is a connection between his mental state and the commission of the act.[1] Constitutional development, coupled with a firmly established conclusion as to the safety of the examination and cross-examination, is dependent upon those participating. The level of performance can scarcely exceed the capabilities of the individuals taking part in the proceedings. Doctors should be able to carefully assess the attitudes of relatives and friends of the plaintiff or defendant. Naturally, by their presence and testimony, a keen observer will know them.

Criminal Responsibility

Criminal responsibility in our state is determined by the McNaughten Rules established one hundred and twenty-two years ago in England. These may be essentially stated as follows: "To establish a defense on the ground of insanity, it must be clearly proved that, at the time of the committing of the act, the accused was laboring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing; or, if he did know them that he did not know that he was doing what was wrong."

Some doctors and lawyers feel that this is an inadequate test. Hundreds of articles have been written in support or in criticism of the McNaughten Rules. The District of Columbia in 1954, in the Durham Decision, revived under a different name essentially the same rule as was established in 1887 in New Hampshire by Judge Doe. This test has remained in effect in New Hampshire to the present time and may be stated as follows: "An accused is not criminally responsible if his unlawful act was the product of mental disease or mental defect."

---

*Former consultant: Hastings State Hospital; the Youth Conservation Commission; Department of Public Institutions, State of Minnesota.

Attempts have been made to clarify and codify more appropriate rules. In 1960 the American Law Institute issued the following test for insanity: "(1) A person is not responsible for criminal conduct if, at the time of such conduct as a result of mental defect or disease, he lacks substantial capacity either to appreciate the criminality of his conduct or to conform his conduct to the requirements of law. (2) The terms 'mental disease or defect' do not include an abnormality manifested only by repeated criminal or otherwise anti-social conduct."

This rule has not been adopted by any jurisdiction that I know of; therefore, the expert witness must regard himself as a guest in the house of law and behave accordingly, i.e., play the game by the house rules.

There are always differences in the attitudes and opinions of physicians participating in a murder trial. These differences might be resolved if each doctor had at least five years' experience working in a state or federal training school, reformatory, prison, and mental hospital: not in just one of these facilities but in all of them, so that he could understand the longitudinal and cross-sectional history of the accused.

The Accused

There are many disorders that are frequently the subject of expert testimony. These include: (a) sociopath with and without psychosis, (b) paranoid schizophrenia, (c) prison psychosis, (d) emotionally unstable personality with sudden uncontrollable rage, (e) temporal lobe seizure, (f) general paresis, (g) postencephalitis, (h) mental defect with and without psychosis. Since opinion varies and no two cases are exactly alike, the possibility of episodic psychosis or the latent explosion of a confinement reaction or hidden psychosis is certainly overlooked in the transmission to the court of a negative finding such as "not psychotic."

The Sociopath

The most common diagnostic category of individuals who are the subject of criminal law proceedings is the sociopathic personality. The diagnostic criteria are well-documented by Silverman,[2] who found essential similarity with no fundamental difference between the criminal and noncriminal sociopath. These traits vary and may not be as extreme as the following description.

"In the absence of psychotic symptoms or a definite neurosis, noteworthy abnormalities in behavior are the signposts for recognition of the sociopath. A longitudinal review of his life reveals behavior which is reckless, impulsive, unrepressed and often bizarre and pointless. In relation to society he is unproductive, parasitic, and antisocial. In relation to his fellow men he is insincere, untrustworthy, irresponsible, sometimes overbearing and demanding, and often outright hostile. Affect is cold, humorless, and lacking in qualities of genuine warmth, gratitude, and remorse. Close interpersonal relationships are never developed, and the sociopath remains extremely narcissistic and selfish. Sexual relationships are promiscuous, inadequate (deficient) or perverse, and are always lacking in real feeling tone for the object. Efforts are unsustained, interests are fragmentary, and there is lack of any consistent life plan. Although sometimes there is an appearance of brilliance, thinking is superficial and at a plane far below that anticipated from the psychometric test level. If the patient recognizes his difficulties at all, projection thinking is the commonest method of rationalizing them. There is often total disregard for the truth. Insight is usually absent, although one is sometimes confronted with superficial verbal insight. Anxiety is rarely manifest, and then only in response to situational difficulty (e.g., incarceration) which the sociopath has brought on himself. Tolerance to frustration or tedium is poor, and this trait may result in unprofitable, impulsive violent acts, temper tantrums or evanescent psychotic-like behavior. Despite their unsavory and anti-social qualities on cross sectional review, many sociopaths appear superficially intact, pleasant, and likable. It is often only by long contact that the underlying chaotic and sick personality is revealed."

The Lawyer

The personalities of the lawyers also play a role. Those representing the prosecution are merely asking that justice be served and society protected. Those representing the defense bewail the injustices done to the prisoner by uncontrollable forces in society and harass the jury they address with the unfortunate circumstances surrounding the crime. The defense attorney, when unable to predicate facts to the judge and/or jury, strives with the patience of Sisyphus* to indoctrinate his listeners regarding moral aptitudes and social values and their relationship to the defendant. He usually strives to formulate the insanity defense, (viz., that the accused was legally "insane" at the time of the alleged criminal act).

Discrediting the Physician's Testimony

Some lawyers are so wholly convinced of the righteousness of their opinions that they approach the courtroom with schemes to publicly discredit the physician. One might say that physicians who have had little or no court experience should realize that the advocate who harasses and attempts to humiliate a medical witness has already been largely discredited.

Too frequently a physician, about to give medical testimony, has but a one-sided version of the trial issues. Interested patients and their friendly informants might well cooperate by giving only favorable items of information at the unsuspecting doctor's examination.

Others, in their studies, acknowledged the following: "In court the fact that many or all of the participants are unqualified to judge the opinions of an expert witness, or the definitions used by the opposing psychiatrists, leaves all the suggestive powers in the hands of the psychiatrist, regardless of his limitations, who may advise the prosecution — simply because he is the one who has the last word and is inadvertently being directed by his legal counselors, their ingrown jargon and way of thinking."[3]

Explosive Words and Phrases

Further, it has been known for many years that highly explosive words have a serious effect on the jury or the court: words such as communist, atheist, traitor, epileptic, homosexual; and the injection of phrases, such as altered consciences, some impulsiveness, moderately changed, and slight degree, tends to confuse those charged with the operation of justice.

Some colleagues inadvertently use these emotionally supercharged words or phrases to stir up feelings. They consider this technique proper and acceptable for the strategy at hand; however, they cannot always control the effects. The courtroom appears then as a means for the promulgation of suggestion and autosuggestion.

"Well, when human nature falters at times we start planning new laws or procedures. I want to reiterate that the common weaknesses in human nature cannot be overcome simply by the enactment of more laws; is that not obviously so?"[4]

Environmentalists

Furthermore, in recent years we have noted the influence of so-called environmentalists who cry for more and more paternalism. If only we relieve or eliminate this and that type of strain, they argue, we will reduce the incidence of antisocial behavior. Past experience in various parts of the world, where and when emotional stress was most severe, has indicated that neuroticism almost wholly vanished in individuals who had not been freed of their complexes by psychoanalysts! We do admit, however, that parental and group attitudes and behavior greatly influence character development in the adolescent.

As long as we have individuals who are unconsciously but totally dedicated to their own specific cause, and the need to satisfy the revenge and hostility in their own psychobiological structure prevails, they will inadvertently substitute the pomp, ritual, and splendor of the courtroom for common-sense thinking about crime and punishment.

Criminal Proceedings

Criminal proceedings stir emotions. Can

---

any judicial procedure compare with the emotional impact of certain criminal proceedings? Conflicting testimony is sought; and the laws are plain, particularly those defining insanity as related to criminal proceedings. Intent in advance and competence to understand the ethics of his acts clearly leave other personality characteristics no weight for mitigation. True, there are few to weep for the victim, and those who know the accused wish him no more bad luck than can be avoided in spite of the predicament into which he has gotten himself.

Any judicial proceeding which receives widespread newspaper coverage exerts emotional pressure on those who read the newspapers. Therefore, not only those immediately involved in the trial, but John Q. Public also becomes emotionally involved; because each of us suffers from some repressed feelings or conflicts associated with injustice and inequity in his early years of growth and personality development. This, more than anything else, conditions and corrupts a person's attitudes; and at a conscious level one must clearly realize that, without a deliberate attempt to manipulate, environmental stress becomes an impediment to one's independent thinking.

Other authors[5,6] agree that the expert cannot answer a question directly, but always has to answer the implications of a question in order to avoid the semantic trap frequently used in due process. For example, the physician who replies yes to the following questions: (a) Did the defendant know that he had a knife in his hand?, (b) Did he know that he was stabbing the victim?, (c) Did he know the resistance of that part of the body at the time of the stabbing? — finally must concede that the defendant knew that he was doing wrong. Many forget that the prosecuting attorney has used the verb "to know" in different connotation and not always in the sense of morality: that is, knowing the nature and quality of one's act.

The Witness

The psychological impact of taking the stand for examination and cross-examination places the witness in an inferior position. The strain of cross-examination is well known even to the point of exacerbation of psychosomatic disease, depressive reactions, and also acute coronary artery disease.[7] Under the stress of cross-examination, a person may find himself adhering to opinions he never held. He can be so swayed by his own feeling of guilt (hostility) that, as a witness, he may agree to anything. Some individuals have such a desperate need for approval that they readily give in to a stern cross-examiner. I have several times observed how an intelligent, expert witness, under careful cross-examination, will gradually concede and even contradict his own better decisions and judgment.

Only knowledge and experience can bridge the gap between good intentions and good performance. Using the present judicial system and conforming to the laws in our state, the nondiagnosis of other observers proves to be only a semantic disagreement.

There come to mind instances of murders by adolescent boys. In many, schizophrenia was operative, though in some there was little evidence of this abnormality. Quite understandably the jurors could see only the act of unmodified guilt and dastard criminality. Incidentally, some of these adolescents were adjudged insane by the examining physician at the penal institution following their reception there, and were subsequently transferred to the Minnesota Security Hospital to be detained there until their recovery.

Self-perjury

A physician interrogated in a court necessarily feels exposed. This provokes defensive mental attitudes that become harmful. Aggressiveness frequently causes the witness to say too much. Stuttering, periods of quiet, nervous gestures and the like are frequently interpreted as arising from guilt. One wonders if any person can recognize and understand the subtle subterfuges in a long court session. Many physicians, colleagues, and demagogues alike in neurology and psychiatry, who have served as expert witnesses, have admitted that while under cross-examination they themselves frequently feel on trial and even "almost convicted." The expert never has a chance to explain any multiple-factor theory to a jury. Every official investigative power can easily become a coercive power. Cross-examination, then, is frequently used as a form of emotional exercise doing disservice to factual evidence, and frequently does not get at the truth of the matter per se. This form of self-perjury and consequent self-justification is a well-known passive psychic defense mechanism.[8]

Retribution

Punishment as retribution rarely prevents crime. It may be said with certainty that society, through a group of individuals, takes part in the emotional involvement of a trial. Everyone unconsciously wants to use the paradox of punishment of others in order to relieve tension and conflict in himself. Suggestion, whether conscious or preconscious, perpetuated over the years in due process, social gratification, and prejudice, becomes part and parcel of courtroom procedure. Many people are unable to live out of reach of mental corruption, and their own personal emotional drive seduces them into acting against their moral principles. It is for these reasons that, with recognition of the emotional impact on the seemingly benign courtroom appearance, the expert, through lack of experience and lack of association with due process and the like, can, through no fault of his own, become involved to such a degree that he loses sight of and ignores the goal before him.

A neuropsychiatrist is trained above all in the methods of science. Objectivity is his goal. More so than lawyers, he is expected to free himself from emotional bias; and as his work demonstrates and reflects a closer attainment of this goal, he will better serve the processes of justice when health and welfare are concerned. Engaged as we all are to seek and apply the truth, it is imperative that we should ever be on our guard against the temptations of exaggerated self-interest and also against the actions of a too sectionalized professionalism. The same principles apply, of course, to men in all professions. For it is a fact that mere technical competence does not suffice for the individual, for the profession, or for democracy.

Experience, therefore, allows one to give an unbiased, well thought-out, and clean-cut testimony relevant to factual evidence and criminal intent, and always triumphs over emotional, as well as personal prejudices.

"Experience is the most efficient teacher of all things:" Pliny.

Overcoming Obstacles

A biologist tells how he watched an ant carrying a piece of straw which seemed a big burden for it. The ant came to a crack in the earth which was too wide for it to cross. It stood for a time, as though pondering the situation, then put the straw across the crack and walked over upon it. What a lesson for us! The burden can become the bridge for progress.

— War Cry

Most of us carry our own stumbling block around with us; we camouflage it with a hat. — Mary Alkus

WHAT'S YOUR DIAGNOSIS?

The patient is a 65-year-old Norwegian farmer who had enjoyed a lifetime of excellent health until three years ago when he began to develop peripherovascular symptoms in his feet and ankles: mainly a cold sensitivity that required long underwear, wool socks, and fur-lined shoes for comfort. Within a year amputation of all his toes was done because of gangrene. One year ago he developed an acute heart failure associated with a hemoglobin of 6 grams. All studies including a bone-marrow examination and GI x-rays were normal. His hemoglobin returned to normal with a "shotgun hematinic" and his heart failure was easily controlled with digitalis.

He was now again hospitalized for study because of increasing pain in his feet and ankles. An oscillometric study markedly decreased total circulation in both legs, but all pedal pulses were full and bounding. An arteriogram showed some irregularities but was within normal limits for his age. X-rays of the legs revealed a generalized osteoporosis. A unilateral sympathectomy was done with no benefit. The pain in his feet and ankles continued to the point where he desired an amputation. Scattered areas of his lower extremities gradually broke down with multiple superficial ulcerations, petechiae, purpura, and superficial thrombophlebitis. The skin color of the legs when in dependent position was usually a mottled, deeply blue color, but on bed rest in the hospital the skin color returned to a more normal, pale, waxy hue. The purpura was usually transitory, but would not blanch on pressure. He was being considered for further amputation in order to obtain relief from pain. The diagnosis was finally substantiated with a laboratory test that could be run in the home with no special equipment.

What is your diagnosis? Turn to page 1177.

Magic Transfer of Disease

In Pliny's medicine there are a number of examples of what may be called magic transfer, in which the aim of the procedure is not to cure the disease outright but to rid the patient of it by transferring it from him to some other animal or object. Intestinal disease may be transferred to puppies who have not yet opened their eyes by pressing them to the body and giving them milk from the patient's mouth. They will die of the disease, when its cause and exact nature may be determined by dissecting them. Griping pains in the bowels will also pass to a duck that is held against the abdomen. One may be rid of a cough by spitting in a frog's mouth or cure catarrh by kissing a mule, although in these cases we are left uninformed whether the disease passes to the animal. But if a person who has been stung by a scorpion whispers the news in the ear of an ass, the ill will be transferred to the ass.*

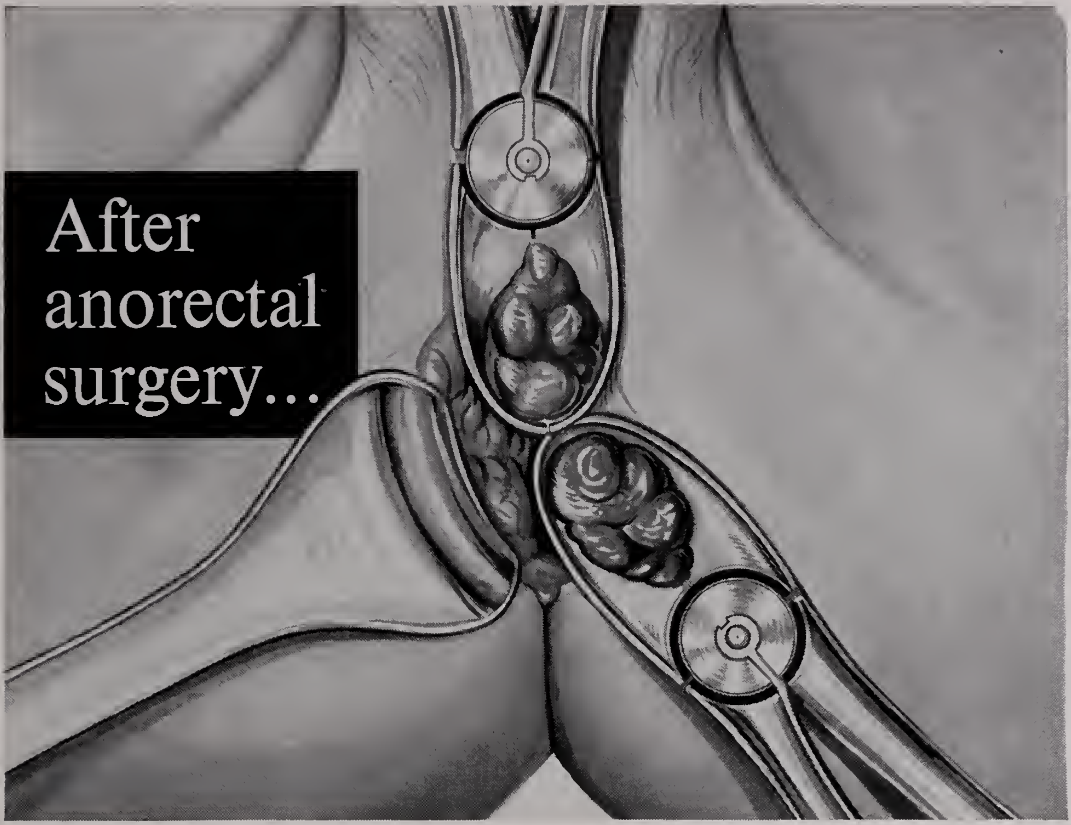
Nature gets more dependent on man with each generation. My father rose high with little more than muscle and courage. But in my time I had to add germ killers, and now my kids need vitamins, psychiatry, and miracle drugs.

— Better Homes and Gardens

If fate throws a knife at you, there are two ways of catching it — by the blade and by the handle. — Oriental proverb



METAMUCIL®

brand of psyllium hydrophilic mucilloid

softens...protects

THE PROBLEM of physical irritation of raw, postsurgical anorectal areas is frequently urgent. A well-verified satisfactory solution to it may be found in the bland, easily compressible "smoothage" of Metamucil.

The natural vegetable bulk of Metamucil softens intestinal contents and provides a soothing demulcent effect that protects denuded mucosal surfaces.

Metamucil prevents strain and traumatizing evacuations from constipation or cathartics and encourages the restoration of normal colonic function.

Average Adult Dosage: One rounded teaspoonful of Metamucil (or one packet of Instant Mix Metamucil) in a glass of cool liquid one to three times daily. Metamucil is available as Metamucil powder in containers of 4, 8 and 16 ounces and as flavored Instant Mix Metamucil in cartons containing 16 and 30 single-dose packets.

SEARLE *Research in the Service of Medicine*

**Happily,
not all your patients
are overweight**

**but
for those who are...**

Bamadex®
d-amphetamine sulfate (15 mg.) and meprobamate (300 mg.)
Sequels®
Sustained Release Capsules

Most overweight patients could benefit from the appetite control provided by the prolonged anorexigenic-tranquilizing action of BAMADEX SEQUELS: anorexigenic action through the central stimulant effect of the amphetamine; tranquilizing action with only mild sedation through meprobamate; prolonged action through sustained release of active ingredients.
Contraindications: Hyperexcitable and prepsychotic states; patients hypersensitive to meprobamate.
Side Effects: Occasional allergic skin reactions may occur with meprobamate, accompanied by fever, nonthrombocytopenic purpura, angioneurotic edema, hypotension, or bronchial spasm. Drowsiness with or without ataxia and/or alteration in visual accommodation may occur. Effects of alcoholic beverages may be increased by meprobamate. Use with caution in patients with coronary or cardiovascular disease or severe hypertension. Prolonged use may result in dependence. Reactions can occur if drug is not withdrawn gradually.

Views of a Trial Judge on the Medical Witness with Emphasis on the Neuropsychiatrist and the Mentally Ill

I WRITE HERE today as a friend and not a critic of both the medical and the legal professions. All of us, be we doctor or lawyer, take pride in the fact that we are professional men. It is basic that the doctor and lawyer have much in common and are fellow professionals working toward common goals.

Unfortunately, one of our main areas of difficulty, and sometimes downright hostility, has to do with the reaction of the medical witness to his stint in the court room. Medical witnesses have many criticisms of the legal procedure, and some of them are well taken. There must be a realization on the part of the medical witness that the legal system is an adversary system. Naturally, the adversary system is quite foreign to the man of medicine. He is educated and trained and practices under an entirely different tradition. Doctors have to realize that it is the adversary system that leads to the discovery of truth and, further, they will have to learn to live with it because it is here to stay.

On the other hand, of course, it is incumbent upon those of us who operate within the legal system to do our very best to make the system more workable and less, shall we say, "adversary." I do believe that the most serious and sound complaint doctors have is that they are not permitted to rely, in stating their opinion, on reports they have from other experts and in some cases not allowed to rely on the office history. This complaint is well taken. Which doctor, in forming the diagnosis of a patient who has come to him, does not base it, in part, on laboratory reports, findings of a radiologist, or reports from other specialists? Similarly, doctors take the patient's history as a matter of course, and find it an important guide to diagnosis. If the standards of the hospital and medical school are to be brought into the court room, then doctors should be permitted the same freedom on the witness stand to express an opinion based on any information that they consider reliable. Fortunately, the law of evidence is clearly moving in that direction.

The area that is most controversial at the present time in the medical and legal professions is the field of neuropsychiatry and its relationship to crime and the defense of insanity. Our courts have been operating under the M'Naghten Rules for over a hundred years, which basically require that "to establish a defense on the ground of insanity, it must be clearly proved that the accused did not know the nature and quality of the act he was doing or, if he did know it, that he did not know what he was doing was wrong." Many psychiatrists and jurists feel

"All Registered Nurses are Alike"

It stands to reason. They all go through the same training; they all have to pass the same tests: they all have to measure up to the same standards. Therefore, all registered nurses are alike.

That's nonsense, of course. But it's no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more demanding. In fact, there are at least *nine specific differences* involving purity, potency and speed of tablet disintegration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn't so.

You might also say that all registered nurses aren't alike, either.

that this is a bad test at best. However, as yet no scholars have managed to come up with a satisfactory alternative and until that happens, I will, reluctantly, have to be one of those who would resist change.

M'Naghten is denounced as unjust to the defendant. It is called arbitrary in the light of modern psychiatric knowledge, and I agree that it is, but the proposal to replace it with another definition of legal insanity contains two flaws. One is the naked assumption that insanity should bear on the determination of guilt as opposed to the post-conviction disposition of the offender. The other is that the very thesis of the attack upon M'Naghten demonstrates that the proposed substitutes are equally arbitrary and incompatible with the psychiatric view of man. However, it is the court's feeling that the real problem that the neuropsychiatrist is having in criminal cases is due not to the formula laid down by the court but because the psychiatrist has attempted to usurp the role of the judge and jury in cases wherein insanity is pleaded as a defense.

Unfortunately, the psychiatrist of today in many instances has attempted to become the expert in sociology, anthropology, philosophy and law. He has attempted to answer questions of legal significance pertaining to mental status — legal, moral, ethical, philosophical questions — instead of straight psychiatric problems. Man has been debating these issues for centuries and has not resolved the difficulties. An entire system of law has been devised to deal with these polemics as they affect social transgressions. However, this resolution belongs in the province of the judge and jury. While it is true that psychiatrists have a special knowledge as to medicine and mental illness, when it comes to the recognition of responsibility, which is a moral and legal problem, their knowledge is no greater than that of the minister, philosopher or judge.

Dr. Robert Jeub in his excellent article in this issue,* entitled "Reflections of a Neuropsychiatrist in a Court of Justice," falls into this error. It is apparent from his reaction to court work that he fails to realize that the majority of neuropsychiatric problems arise from the witness extending himself into fields in which he has no business. His reference to the fact that prosecutors are merely seeking justice and defense attorneys something less constitutes naivete at its worst. Perhaps it would be much better if experts in all fields, including neuropsychiatry, learned the use of the words, "I don't know," when the examiner tries to lead them outside their special field of knowledge.

In fairness, it must be admitted that the experts in the psychiatric field have been driven to some extent by the public and by the courts and the lawyers in expending their area of *expertise*, because lawyers and courts have wrongly continued to ask their help in problems outside their special field. Actually, this trend has been unfair to the psychiatrist, who may be of great help to the courts if his testimony is confined to medical-psychiatric issues rather than to the greater issues of morality and legality.

It is the awesome responsibility of the law to determine when a man is responsible for his behavior, and it is the duty and the responsibility of the psychiatrist to help the law make that determination by sharing with the law only his knowledge of mental illness and its relation to behavior. If psychiatrists were held to their special medical knowledge in the court room rather than attempting to extend it to areas not within their special domain, they would escape with less drastic results to the sanctity of their offices.

Therefore, it is imperative that the psychiatrist, the lawyer and the court work together to leave the moral questions involved and the opinions of responsibility to the court, with the aid and assistance of good forensic psychiatry confined to its speciality of medical knowledge.

The truth is that insanity should have nothing to do with the adjudication of guilt but rather should bear only upon the disposition of the offender after the conviction and, therefore, the contest concerning M'Naghten and its competitors is a struggle over an irrelevancy.

Lawyers, by improving their treatment of

Doctor Wangensteen

THE READERS OF this issue of MINNESOTA MEDICINE* are given a real treat through the publication of Doctor Wangensteen's recent address to the Minneapolis Surgical Society. Here a great surgeon declares his philosophy and beliefs and, in doing so, makes more understandable his ability to stimulate and develop the maximal potential in the young surgeons who have worked under his direction.

For those of us who know, love and admire Doctor Wangensteen, his modest estimates of his own contributions to one of the most productive departments of surgery in the history of medicine, his concise and perceptive review of key contributions to surgical advancement and his sense of direction toward future progress in the surgeons' attack on disease are both impressive and delightful.

It is probably because he has always served in an academic environment that the comments of one who is in private practice of surgery has been solicited.

Doctor Wangensteen has stated emphatically that a man cannot serve two masters at a time. He cannot pursue a productive life as an academic and research-minded individual and also meet the pressing demands of a large clinical practice. Only the suitably endowed and motivated can be effective and happy in the academic environment. The majority must devote themselves to and find satisfaction in rendering the highest quality of surgical care to the public.

The division into two groups should not be absolute. Indeed, the clinical surgeon is essential to good teaching. He is making his contribution toward better surgical care and is keeping himself alert and lessening the gap between new knowledge and its application.

Nevertheless, our skyrocketing progress in the field of surgery and our ability to give the public the benefit of these improvements depend upon the effective marriage of these differently oriented groups. The analogy of marriage carries with it the inevitable misunderstandings, minor quarrels and the requirement of mutual respect inherent to this venerable state.

Rapid changes in the attitude of practice have already occurred and will continue. We can hope that these changes will be evolutionary rather than revolutionary, for thus has surgery and all medicine progressed, keeping what is good and adopting what is new and better.

Must we destroy a system that has done so much for American medicine in order to conform to a pattern more suitable for governmental activity in medicine and completely adaptable to the aims of a large group who wish government to take over completely?

I can best comment on the future of surgery by offering areas of concern, which I am sure are shared by many. In essence we wish to preserve our present system, making what changes are needed to give all the benefit of the best care and preserving the working relationship between teaching, research, and the actual delivery of services.

Naturally, my first concern is the direction in which and the degree to which government will step into the picture, usurping administrative functions best understood and served

Smith Kline & French Laboratories SK&F

by physicians. Government encroachment will, of course, affect private practice more than the academic field. Even in the latter, there is cause for alarm; for government, not listening to us and not realizing that it is easier to build schools and laboratories than to find and train competent, research oriented people to man them, threatens to overwhelm our already established and productive teaching institutions.

I am concerned lest the need for highly-trained surgeons exceed the ability of our institutions to utilize the currently accepted best method (dog laboratory) for training them. In such a case, our surgical educators must turn more to the clinical training programs used successfully for so many years. Feeling that the "compassionate graces" are more easily acquired when working with people, there are many surgeons who favor clinical training. Perhaps the laboratory method can be used for those heading for academic careers and clinical training for those planning private practice. A reasonable balance between these two methods is ideal.

With respect to planning careers, I am concerned that trainees shall not be influenced into academic careers unless their interests and aptitudes justify this choice. They should understand that idealism is not exclusively the badge of the academic surgeon; that there are teaching opportunities and immense satisfactions aside from monetary rewards in the private practice of surgery.

The large sums of money poured into our teaching institutions by the government for research, approximately $1,000,000,000 annually, are creating pressures in our medical schools which cause concern for all of us.

The emphasis on research and the consequent demand on the time and thought of our faculties threatens the quality of teaching of our undergraduates. Where this threat is real, it demands the authoritative intervention by departmental heads.

Another effect of the accelerated research programs in American medical schools is the intense, often bitter, competitive spirit it engenders in those participating. Recognition and progress in the academic field depends for the most part on research productivity. There is a temptation, which must be resisted, to publish results and to recommend procedures before they have been thoroughly tried and their value established.

As long as this country can produce its Wangensteens, and it can, the American public is assured of progress in the field of surgery as dramatic as that already achieved. Our danger lies in the threat of revolutionary changes in administering our services to the public. We are obligated to continue our study of these trends, to keep the public informed and hopefully expect the public to defend themselves against damage through the interposition of government between their doctors and themselves.

entire self and energy to his cause — and not to be deprived for trivial injury. This is the dilemma of the field-side physician.

His decision must be swift and authoritative, fair, and uninfluenced by the honest pressures of the day. He must, then, have guidelines for decision — objective findings and evaluations — thoughtfully prepared for his moment of truth. A series of articles to present such guidelines makes its appearance in this issue of MINNESOTA MEDICINE.* The series is planned under the sponsorship of the Minnesota Committee on Trauma of the American College of Surgeons, through the good services of Dr. Frederick Drill, Minneapolis, and Dr. William Nolan, Litchfield. We commend it to the interest of any doctor who may find himself "on the spot" with an athletic injury.

Mathematics and Medicine — Medicometrics

MATHEMATICS IS without any doubt the most exact means of expression and communication that man has today. It is his most inflexible and relentless language. In it he has sought to express all the laws which govern the most primitive mechanics, as well as the infinitely complex cosmos. Mathematics is man's most versatile tool and perhaps one of his oldest.

At the dawn of human awareness man had two choices in the matter of directing his future and acquiring mastery over it. The first was perfecting his own body — by seeking, formulating and expressing reasonably exact laws of vital mechanisms and chemisms* and, in this way, establishing life on a surer basis. The second and more obvious was examing the laws of the universe and reducing them to exact and rigid principles. The most important subsidiary activity was localizing the universal; i.e., building machines in miniature duplication of general universal laws.

The second of these alternatives was the one primitive man chose to follow. He was more interested in constructing a bow and arrow (an attempt to apply primeval mathematical physics to reality) than he was in trying to arrive at an exact understanding and mathematical expression of this vital phenomenon. The physical sciences are, therefore, the more primitive. Early man was more interested in constructing a canoe or a bridge than he was in understanding his own body. The universe was dissected aeons before the organism. This was, perhaps, a very natural thing, for man loves comfort more than he does security of existence.

Modern civilization has been built essentially on a basis of mechanical engineering instead of biological engineering. Our achievements in formulating the laws of astrophysics are phenomenal; but our attempts to reduce biological phenomena to exact mathematical formulas are puny.

The sciences fall into two very broad categories: the biological and the physical. Of the two, the physical sciences are characterized by their mode of expressing their facts and observations in exact and invariable language: mathematics. Mathematical formulas represent tangible facts. The biological sciences have been characterized by a lack of technical language whereby to state their

Butazolidin®
brand of
phenylbutazone

in
osteoarthritis

Geigy

Therapeutic effects
A number of investigators report improvement in about 75% of cases. Relief of pain and stiffness is the predominant response. Frequently, there is also a significant improvement in function. The beneficial effects of the drug are usually seen by the third or fourth day of treatment.

There is general agreement that milder cases of osteoarthritis are preferably treated by simple analgesics. In many patients, however, this mode of therapy fails to give sufficient relief. Because steroids are not very effective in this form of arthritis, phenylbutazone affords the drug therapy most capable of relieving the more severe cases. For best results, it is recommended that treatment with phenylbutazone be combined with physiotherapy and other appropriate supportive measures.

Dosage
The initial daily dosage in adults is 300-600 mg. in divided daily doses. In most instances, 400 mg. daily is sufficient for maximum therapeutic response. A trial period of one week is adequate to determine the effects of the drug; if there is no improvement, discontinue the drug. When improvement does occur, dosage should be promptly decreased to the minimum effective level: this should not exceed 400 mg. daily, and is often achieved with only 100-200 mg. daily.

Precautions
Before prescribing, the physician should obtain a detailed history and perform a complete physical and laboratory examination, including a blood count. The patient should be kept under close supervision and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools. Regular blood counts should be made. The drug should be used with greater care in the elderly.

Warning: If coumarin-type anticoagulants are given simultaneously, the physician should watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea and sulfonamide-type agents and insulin. Patients receiving such concomitant therapy should be carefully observed for this effect.

Side effects
The most common side effects are nausea, edema and drug rash. Infrequently, agranulocytosis, generalized allergic reaction, stomatitis, salivary gland enlargement, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia are also possible side effects. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently.

Contraindications
These include: edema, hypertension, or danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. Because of the increased possibility of toxic reactions, the drug should not be given when the patient cannot be seen regularly, when the patient is senile, or when other potent chemotherapeutic agents are given concurrently. Large doses of Butazolidin® alka are contraindicated in patients with glaucoma.

Note: The physician should be fully aware of dosage, precautions, side effects and contraindications as contained in the complete prescribing information.

Butazolidin alka

Each capsule contains:	
Butazolidin, brand of phenylbutazone	100 mg.
dried aluminum hydroxide gel	100 mg.
magnesium trisilicate	150 mg.
homatropine methylbromide	1.25 mg.

Butazolidin
brand of phenylbutazone
Tablets of 100 mg.

fundamental facts. It is for this reason, among others, that medicine cannot be called an exact science, while physics can. The mathematics of biology has not as yet been as fully developed as it might be.

There have, however, been several attempts in the right direction. W. J. V. Osterhout some years ago endeavored to apply quantitative measurements to the processes of life. He attempted to arrive at mathematical formulas to indicate just how much a plant or an animal cell is alive, or how near to the zero point, death. His book, "Injury, Recovery, and Death," is a classic in the nascent science of biological mathematics.

The vital process may be conveniently reduced to a statement: life is the mathematically harmonious relationship among the vital centers of the organism. Physiology has established what these vital centers are, but we have no mathematical formulas which can give us a conception of the complicated interaction among these organs. A calculus of this would, in fact, reduce life to a series of mathematical formulas.

Some time ago Ellice McDonald made an attempt to reduce life to a chemical equilibrium:

$$\mathrm{K} \; \frac{\mathrm{H_2CO_3} \times \mathrm{H} \times \mathrm{S_o} \times \mathrm{E_r}}{\mathrm{BHCO_3} \times \mathrm{CH} \times \mathrm{S_r} \times \mathrm{E_s}}$$

In this formula, K is the protein constant of protoplasm; $BHCO_3$ is the fixed alkali of univalent cations; H_2CO_3, is the fixed acid of bivalent* and trivalent* cations and all anions; OH represents free hydroxyl ions; while H represents free hydrogen ions; Sr represents the reduction part of the oxidation-reduction poise, in the sense of Maxfield Clark; So is the oxidation part of the oxidation-reduction poise of Maxfield Clark; Es represents the sympathetic effect of producing emotions; while Er is the vagus effect producing emotions. In this formula, the equilibrium of life is determined by the protoplasmic constant K. In the upper bracket are the environmental influences producing changes. While this is not a very complete formula, it is an interesting attempt, a groping in the right direction.

Within more recent years Nicholas Rashevsky has been applying mathematical concepts to biology; he is perhaps the first of the modern pioneers in this new discipline. His book, "Mathematical Biophysics," first published in 1938 and since then revised and enlarged in several successive editions, is a pioneer effort in an entirely new direction. Rashevsky has applied mathematical interpretations to the theory of embryonic development, the theory of cancer, cell division, perception of visual processes, learning, logical thinking and abstractions, among many others.

It will be many years before we have a theoretical biology comparable to a theoretical physics. The heartening thing is that very encouraging beginnings are being made.

Editor's Note: Progress is being made in all fields of medicine. Why not medicometrics? Perhaps some day we can each write our own eugenic pedigree into the formula.—C.O.R.

Astrology and Medicine

The planet Mercury, when malefic, predisposes to nervous disorders: aphasia, amnesia, headaches, neurasthenia, and other pathologies involving the brain and nerves. The occult Mercureal influence is continuously operative in human destiny even though the planet itself is seldom visible to the naked eye because of its close proximity to the sun, whose dazzling light obscures the small satellite.

On rare occasions, however, Mercury can be detected as morning or evening star, preceding the rising or following the setting sun.

Pleasant words are as an honeycomb, sweet to the soul, and health to the bones.
— Proverbs 16:24

to help relieve pain in common anorectal disorders

"non-caine"

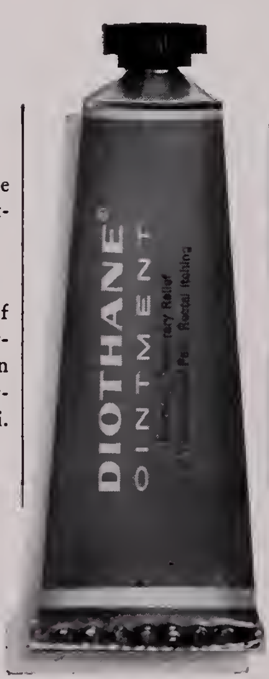
Diothane®

Diothane—with its chemically distinct "non-caine" anesthetic agent diperodon—provides effective temporary topical anesthetic and emollient actions for soothing relief of anorectal pain. Anesthetic activity is effective and relatively prolonged; sensitization is infrequent. Reports to Merrell on 1,500 patients treated pre- and postoperatively with Diothane Ointment, indicate only 22 developed local skin reactions. Reactions to Diothane have been burning or stinging sensations and a few cases of allergic manifestations. An additional advantage: Diothane Ointment and Suppositories are mildly antiseptic. Prescribe or recommend either form...both are now available.

DIOTHANE OINTMENT

COMPOSITION:
diperodon 1.0%; oxyquinoline benzoate 0.1% in a special ointment base.

INDICATIONS:
Provides temporary palliation of pain that may result from hemorrhoidectomy and from common anorectal disorders such as hemorrhoids, anal fissures, pruritus ani.



CHILL
PULL APART

DIOTHANE SUPPOSITORIES

COMPOSITION:
Each suppository, weighing approximately 2.6 Gm., contains diperodon 1.0%; urea 10.0%; oxyquinoline benzoate 0.1% in a special hydrophilic suppository base. A unique shape keeps the suppository in intimate contact with mucous membranes.

INDICATIONS:
Provide for temporary palliation of pain caused by hemorrhoids and pruritus ani.

Letter to the Editor:

In a recent issue of MINNESOTA MEDICINE[1] attention was drawn to Troisier's sign, the presence of an enlarged left supraclavicular lymph node indicative of advanced carcinoma of the stomach. My interest was aroused because I had been taught that this was Virchow's gland, in honor of the great German pathologist, Rudolf Virchow (1821-1902), the founder of cellular pathology, creator of the doctrine of embolism, and public official in Berlin. I was not familiar with Troisier.

A little research, with the assistance of Mr. Thomas E. Keys, Librarian at the Mayo Clinic, disclosed that Charles Emile Troisier was an excellent clinician and pathologic-anatomist of Paris who lived from 1844 until 1949. One of his major contributions, in 1874, was a study of the spread of cancer through the lymphatics. He devoted special attention to cancer of the thoracic duct and to the involvement of the supraclavicular lymph nodes. This involvement may indicate a primary cancer of the thoracic cavity, the stomach, intestine, liver, pancreas, kidney, uterus or uterine adnexae.

Miltown®

An eminent role in medical practice

- Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.
- The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.

Miltown®
(meprobamate)

Indications: 'Miltown' (meprobamate) is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, 'Miltown' fosters normal sleep through both its antianxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of preexisting symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: In two strengths: 400 mg. scored tablets and 200 mg. coated tablets.

Before prescribing, consult package circular.

WALLACE LABORATORIES
Cranbury, N.J.

CM-5761

A woman, aged 72 years, consulted me because of pain in the abdomen of two weeks duration. The pain radiated into the chest and to the interscapular area. On examination, enlarged lymph nodes were found in the left supraclavicular area and there was a hard, movable mass in the left upper abdominal quadrant. Pathologic examination of the excised left supraclavicular lymph node revealed rapidly growing metastatic adenocarcinoma. The sign of Troisier was valuable in establishing the diagnosis and the patient was spared an exploratory laparotomy.

On many occasions this sign has been useful and revealing to me. I feel indebted to the distinguished French physician whose name it bears and to MINNESOTA MEDICINE for bringing its proper identity to my attention.

The Editor's Soliloquy

Medicare

Perhaps we are on the eve of a new philosophy wherein the social state must be given the responsibility of paying all hospital costs for all people, all medical bills for all people, all drugs for all people. What is there to stop this line of thinking from extending to all items in the drugstore and finally to all commodities, no matter what, for all people — in accordance with their whims and not their needs.

By removing the incentive for personal protection, in a job well done and accordingly remunerated, may we hope that government intervention under the guise of benevolence will not be the opening wedge to initiate decay of the greatest medical progress of all time. Now that we have it, it is incumbent upon us to maintain our equanimity and continue to provide honorable, ethical, high-grade medicine to all our patients.

— Carl O. Rice, M.D.

President's Letter continued from page 1123.

gestions could make the AMA a more efficient, yet representative, organization better able to serve the physicians of this country in an adequate manner. If this is desirable at a national level, it is equally so at the state level. The Committee on Permanent Evaluation of the Minnesota State Medical Association should be encouraged to continue its activity. The essence of the whole thought is to advocate the selection of capable representatives and to allow them to function in a framework designed for efficient operation.

Curbstone Consultation

de Quervain's Disease

QUESTION: I am unclear as to the nature of the pathology in de Quervain's disease. Is the management similar to that for a tenosynovitis elsewhere?

ANSWER: De Quervain's disease is a stenosing tendovaginitis rather than a tenosynovitis. A tenosynovitis is essentially an inflammation of the cellular mucin-producing lining membrane of the fibrous tissue tube — vagina — through which the tendon glides. Treatment of the acute process in such cases usually responds readily to immobilization and hydrocortisone injections directed into the space between the tendon and synovial lining of the tendon sheath.

The stenosing tendovaginitis in de Quervain's disease involves the abductor longus and extensor brevis tendons of the thumb. Stenosing tendovaginitis in contradistinction to tenosynovitis, involves the fibrous wall of the tendon sheath at special regions, rather than the lining synovium of the entire sheath. It occurs where the tendon passes through a fibrous ring or pulley, usually located over bony prominences. In the case of de Quervain's disease this is at the radial styloid process of the wrist. Due to proliferation of the fibrous tissue at this site there is encroachment on the tendon as it passes through the fibrous ring in that region. Finally the tendon becomes constricted by the hypertrophied ring. Definitive treatment for this condition consists in longitudinally incising and partially excising the thickened tendon sheath at the affected site.

Drugs Causing Hepatitis

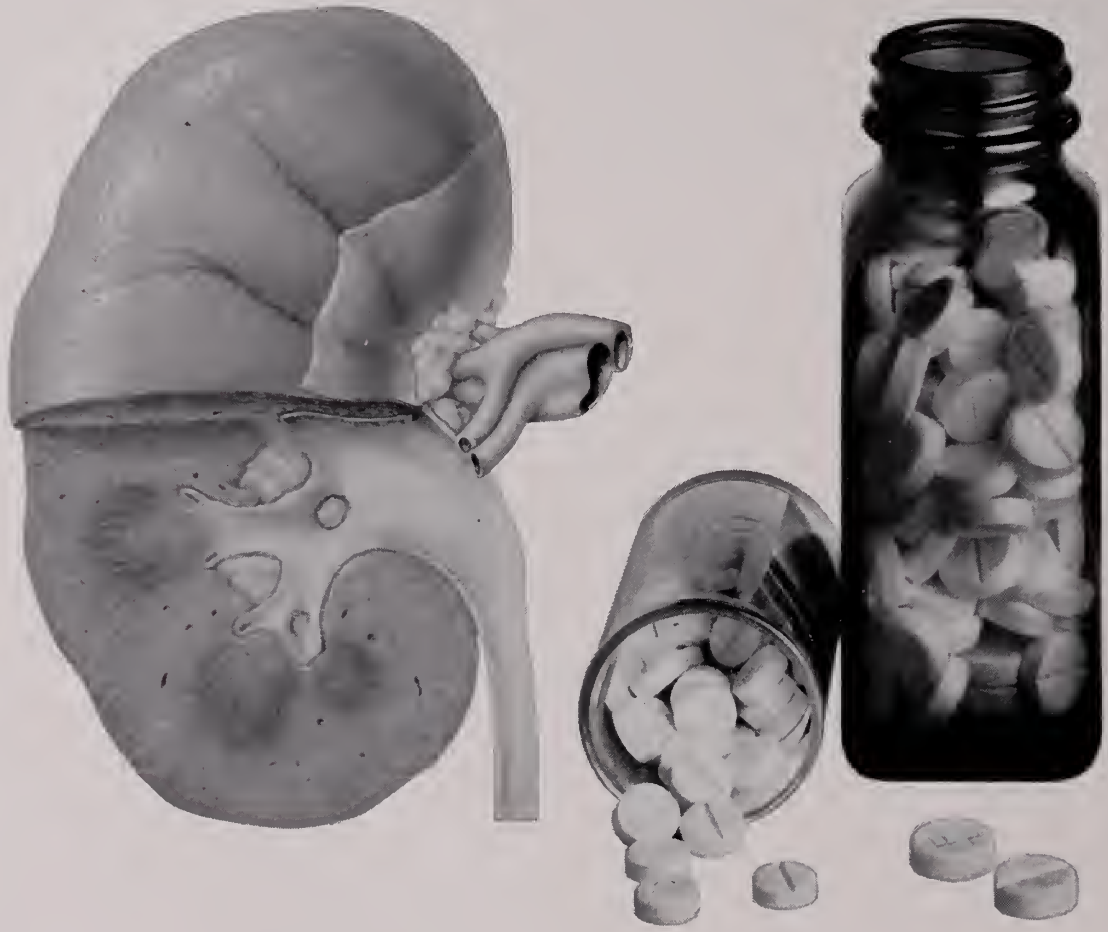
QUESTION: What are the most common drugs causing hepatitis?

ANSWER: Probably the drugs most commonly causing trouble today are the phenothiazine tranquilizers, PAS and the anabolic steroids. The number of viral hepatitis-like reactions, although very serious, is small.

Fenton Schaffner, M.D.
Mt. Sinai Hospital
New York, New York

We can no more escape choosing than we can escape the consequences of our choice. — Cliff S. Emeny, Rule of Law, Freeman

at Merck Sharp & Dohme...



The development of chlorothiazide and probenecid were events of major importance, but perhaps even more important for the future was the Renal Research Program by which they were developed. When Merck Sharp & Dohme organized this program in 1943, it was expressing in action some of its basic beliefs about research:

- Many problems connected with renal structure and function were still undefined or unsolved. The Renal Research Program would begin its basic research in some of these problem areas.
- From knowledge thus acquired might come clues to the development of new therapeutic agents of significant value to the physician.

For example, the Renal Research Program put fifteen years into this search before chlorothiazide became available. But because these years had first led to a greater understanding of basic problems, the desired criteria for chlorothiazide existed before the drug was developed.

Along with other research teams at Merck Sharp & Dohme, the Renal Research Program continues to add new understanding of basic problems—understanding which will lead to important new therapeutic agents.

Fracture–Trauma Conference

Management of Ankle Injuries Sustained in Sports

The doctor on-the-scene has the best opportunity to make an accurate diagnosis and must ultimately determine if and when the athlete with an ankle injury may return to the game. With any injury to the ankle, it is well-advised to bring the player to the side lines, not allowing him to bear weight on the injured extremity. The shoe and taping should be removed, and careful examination carried out. Often it is helpful to examine the normal ankle as well, in order to compare relative ranges-of-motion and stability of the various ligaments.

Quigley[1] has suggested that sprains be graded in severity from i to iv; grade i being the least degree of injury and grade iv being complete rupture. With grade ii sprains properly treated in a cooperative patient, the injury was sufficiently healed to allow full participation in contact sport about eight days following injury.

Athletes in contact sports should have their ankles wrapped for practice sessions as well as in game conditions. Rarick[2] reported that the greatest support was achieved with the basketweave and the combination stirrup and heel lock wrapping. The least support was given by the standard basketweave. He found that as much as 40 per cent of the supporting strength of the strapping was lost after exercise; nonetheless, the remaining 60 per cent of strength certainly affords protection.

Diagnosis

Severe Injuries

In severe injuries involving fractures or dislocations for the first 30 minutes or so the patient usually has very little pain, unless the tibial nerve is being severely stretched. Before pain, hematoma, and swelling occur, the team physician has a "golden opportunity" to manipulate the foot and ankle back to normal alignment. If the foot and ankle are displaced laterally and posteriorly, as is usually the case, the foot should be pulled anteriorly on the tibia and held in inversion. A bulky pressure dressing, using sheet-wadding or cotton held in place with a 6-inch ace bandage, will immobilize the injured part very well. The patient can then be transferred in relative comfort to a hospital for x-rays and further care.

Minor Injuries

Only in minor injuries where there is found to be full range-of-motion, good stability, and no significant pain with stress placed on the various ligaments, should the team physician consider allowing that player to

Continued

return immediately to the game. If there is evidence of hematoma formation, a grade ii, iii or iv sprain must be suspected, and the player must be prohibited from further participation on that particular day. The stability of the collateral and the anterior tibiofibular ligaments should be tested and compared to the stability on the uninjured side. If external rotation of the foot on the tibia causes pain over the deltoid ligament or a sensation of crepitus over the distal fibula, or if there is undue laxity of any ligament, that patient needs further evaluation at the hospital including x-rays.

X ray Examination

X-rays should be taken in three views; these include an AP with the toes straight up, an AP with the extremity internally rotated 20 degrees, and a lateral view. Stress films can be taken; but because of wide variation in the normal talar-tilt angle, a talar tilt of less than 23 degrees is not a reliable indication of rupture of the fibular collateral ligaments.[3] External rotation stress films are of value in determining the status of the deltoid ligament.

Treatment

Ankles which have sustained grade i sprains should be rewrapped if the athlete is to return to participation immediately. After the game, the extremity should be elevated and ice-packed for the first 24 hours. Following that, whirlpool and active exercises will help shorten the period of rehabilitation, will help regain lost range-of-motion, and will provide mild analgesic during the exercise.

Treatment of grade ii and iii sprains should include immediate pressure dressing, ice-packing, elevation, and rest. For weight bearing, the ankle should be supported with either tape strapping or a short-leg walking cast. The patient should be kept on crutches with partial weight bearing until he can walk without pain or limp. This will often take anywhere from seven to twenty-one days. Active range-of-motion can be started when he experiences no pain with the range-of-motion exercises. Under no circumstances should there be passive range-of-motion or heavy massage. Procaine injection into the ankle so that exercise can be carried out is mentioned only to be condemned.

Grade iv sprains are diagnosed when x-rays taken with external rotatory stress on the foot show lateral subluxation of the talus; this means that the deltoid ligament has been ruptured, possibly along with the distal anterior tibiofibular ligament. If there is a diastasis between the distal tibia and fibula, the interosseous ligament has also been ruptured. Grade iv sprains should be treated with a long-leg cast following reduction, the knee being flexed about 20 degrees. The cast should be left in place for six weeks without weight bearing. Post-casting x-rays definitely must be taken to rule out lateral displacement of the talus occurring during cast application. Spiral fractures of the distal fibula without lateral subluxation of the talus during external rotatory stress films, may be treated like grade iii sprains.

Tumor Conference

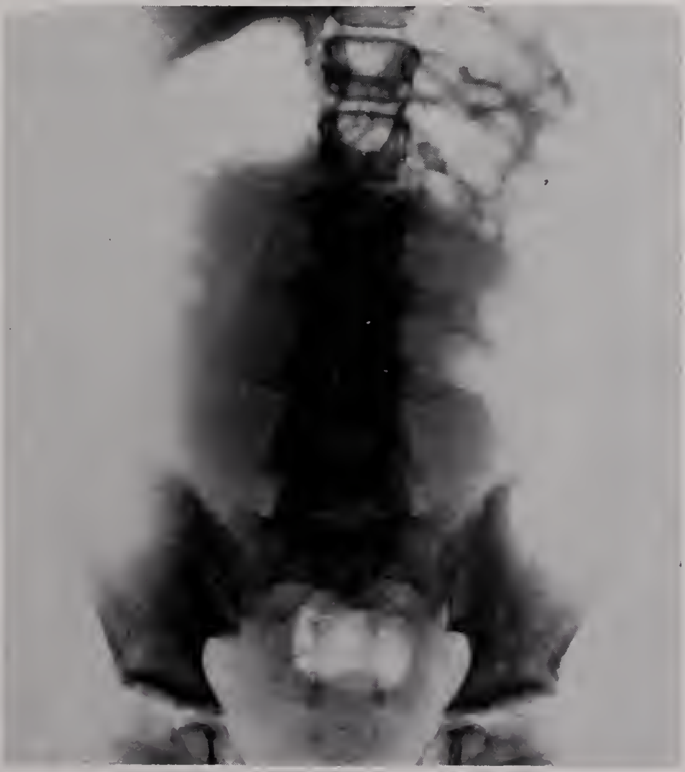
Malignant Ovarian Teratoma in a Nine-Year-Old Girl

The development of a malignant tumor in a child is a deeply distressing problem to both the family and the doctor. Because the child has a period of future growth, certain modalities of treatment are not applicable. The following case history illustrates this problem:

Case History

A nine-year-old white girl was admitted to Swedish Hospital on July 11, 1964, with a three-day history of lower abdominal pain and distension. She had had difficult, infrequent and bulky stools since birth. She had had urinary tract infections twice during the preceding year. A doctor, who examined her at the onset of her pain, thought she might have a fecal impaction as the cause of her abdominal distension; but enemas gave no relief.

On admission, she was not seriously ill. There was moderate abdominal tenderness in the left lower quadrant and a mass extending up to the umbilicus on the left and somewhat lower on the right. X-rays revealed a 22 cm. mass in the lower abdomen. The left ureter was displaced anteriorly and to the left. The intravenous urogram and colon X rays were otherwise normal. A chest X ray was also normal. Hemoglobin was 10.7 grams and the sedimentation rate 68 mm./hour. The white blood count decreased from 12,600 to 8,600 in 36 hours.



Continued

Exploratory laparotomy revealed a large, somewhat cystic mass with an 8 cm. irregular, nodular, yellowish-gray area on one side. There was edema of the broad ligament but no apparent spread of the tumor. The uterus and right ovary were normal. Her postoperative course was uneventful. The first microscopic sections resembled a dysgerminoma, but additional sections proved the tumor to be a malignant teratoma.

Although malignant teratomas are somewhat sensitive to cobalt therapy, the dose required is so large that there would have been marked effects upon the epiphyseal centers of the lower spine, pelvis, and femurs. Because of her young age, this modality would likely have left her severely crippled.

Borrowing from the experience of "second look procedures" in management of carcinoma of the colon, a second laparotomy was performed on October 12, 1964. Biopsies were taken from adhesions to the left abdominal wall, left iliac lymph node, the stump of the left infundibulopelvic ligament and a small nodule on the right ovary. No residual tumor was found either grossly or in any of these microscopic sections.

The girl has remained well and one year after surgery shows no evidence of recurrence.

Discussion

Pathology

Teratomas of the ovary are usually solid, smooth and well encapsulated. About 12% are bilateral. Solid teratomas are most frequently found in young women. The peak incidence is during the second decade of life. Teratomas comprise 15% of ovarian tumors in children. The embryonal and undifferentiated tumors are rapidly fatal, with death usually occurring during the first year.[1]

Most teratomas of the ovary are benign. Kent and McKay[2] reported an incidence of 1% malignancy. Five of their series of 443 cases were malignant. Peterson,[3] in a collected series of 8,038 dermoid cysts, found 147 with carcinoma, an incidence of 1.8%.

Most of the lesions are squamous carcinoma, but other types of tumor have been observed, such as choriocarcinoma, carcinoid tumors and struma ovari (thyroid carcinoma).

Treatment

Gross[4] reported four teratomas in a series of thirteen cases of malignant tumors of the ovary in Boston Children's Hospital. Two died of metastasis within a few months. One was alive and well seven years later and the other fourteen years later.

The best hope for a cure is early gentle surgical removal of the tumor. Cobalt therapy and other cancericidal agents are of limited value. If the patient has attained her growth, cobalt therapy should be used postoperatively.

The extensive radiation required for this radio-resistant tumor would likely result in severe deformities of spine, hips, and pelvis in the actively growing child. Garland,[5] in citing from Wittenburg and Newhauser, states that "almost invariably a tissue dose of over 2,000 r produces discernible bony alteration. This effect is related directly to the dose delivered to the spine and related inversely to the age of the patient."

If the malignant teratoma is apparently completely removed, postoperative radiation is not justified. A "second look" laparotomy in three months is suggested as a means of detecting and removing recurrent tumor.

Summary

Malignant teratoma of the ovary is a rare tumor occurring most frequently during the second decade of life.

It is best treated by careful complete surgical removal.

Postoperative radiation is of limited value and used only after body growth has been attained.

A "second look" laparotomy may be used to control local recurrences.

Elmer J. Martinson, M.D.
Wayzata, Minnesota

ANSWER TO WHAT'S YOUR DIAGNOSIS

(From page 1152)

Cryoglobulinemia. The test — a viscid layer forms when the serum is cooled to 4 degrees Centigrade, and redissolves when the serum is warmed. The exact etiology of the cryoglobulinemia in this case is, as yet, undetermined. Twenty-five per cent will be essential, 50 per cent will be a multiple myeloma, and the other 25 per cent will be divided among chronic liver disease, lymphomas, collagen diseases, and other factors.

The Foodic Again*

A nice, convenient classification of obesity might be first, just mildly obese, which should likely refer to the pleasingly plump individual who is still pretty smoothly proportioned, does not stick out too much here and there, and who may realize, I hope, that it is better to prepare and prevent than to repair and repent.

The second degree of obesity could be termed the stout or corpulent type who bulges fore and aft, and who half talks with his belly which bobbles around like jelly when he laughs. He usually wheezes and puffs, is often knock-kneed, is forever trying to impress his audience of his light-footedness in spite of his flat-footedness.

And at last, there is the really fat individual, whose chins are a part of his chest, who can't speak for fear of over-exerting himself, and if he does happen to move, he flows. He has given up trying to be thinner even next year, worries only about where the ham and potatoes are to come from tomorrow, and has given up the inspection of his hidden bodily acres and acres that he can view only with a mirror.

— F. William Saul, M.D.: Pink Pills for Pale People

Neuro-Pediatrics Conference

Sublingual Thyroid and Acquired Hypothyroidism*

Dr. Samuel Rotenberg:** This white female was born October 22, 1958, of a pregnancy during which the mother had pneumonia in the first trimester. The delivery was normal and the child breathed and cried immediately. The birth weight was 5 pounds, 11¾ ounces, and the neonatal course was normal. At seven months of age, the infant had an upper respiratory infection, and at 13 months of age an episode of otitis media. At this time, her hemoglobin was noted to be 8.5 grams per cent. She was started on iron therapy, and two months later her hemoglobin was 10.8 grams per cent. She has also been given Imferon® injections, but without any change in her hemoglobin. During the next two years, she had multiple upper respiratory infections, otitis media and several episodes of bronchitis. A persistent anemia was noted on these visits and was treated with oral and intermuscular iron. Her hemoglobin ranged from 8.5 grams per cent to a high of 11 grams per cent in September, 1964.

She had received her original series of diphtheria-pertussis-tetanus immunizations in 1959 and Sabin polio vaccine in 1960. In September, 1964, she received her booster diphtheria-pertussis-tetanus shots and her smallpox vaccination; her tuberculin test was negative. The mother, who felt that the child was no different from other children, wanted her to go to school, even though she was shy and withdrawn.

In November, 1964, a conference was held with the parents and the school, and it was decided that a thorough medical examination should be performed because of the child's small height and her shy and withdrawn behavior.

Miss Helen Engelbretson:†

Subsequently the family moved to Omaha for a year and another conference was held prior to the child's starting school in the fall of 1964. As the mother felt that her little daughter was "ready for school," an interview was held with Mr. Rasmussen, a psychologist in the Robbinsdale

Continued

School System. On the basis of his studies, she was placed in a special kindergarten class with Mrs. Lindstrom as her teacher.

Mrs. Maxine Lindstrom*

The patient had had no prior kindergarten experience, and physically she was not on a par with the rest of the children in the class. The only emotion she expressed was on the first day of school, when she cried upon debarking from the bus. Otherwise, she has responded and worked well in class; however, she has shown no enthusiasm for her work, and her small size has set her apart from the rest of the students. At the parents' conference in November, it was learned that she did not talk until she was four years of age, and the mother felt that perhaps she "babied her too much." The parents were then aware of the need for further medical evaluation and thus the referral back to Dr. Rotenberg.

Dr. Mark Mathison**

In the Pediatric Outpatient Clinic in December, 1964, additional history revealed the child's developmental milestones to be as follows: she followed objects with her eyes at two months, rolled over at six months, sat without support at eight months, and walked at one year of age. Single words were spoken at 18 to 21 months, and short sentences at four years. The mother first noted a change in the patient at age two, when she seemed slow in

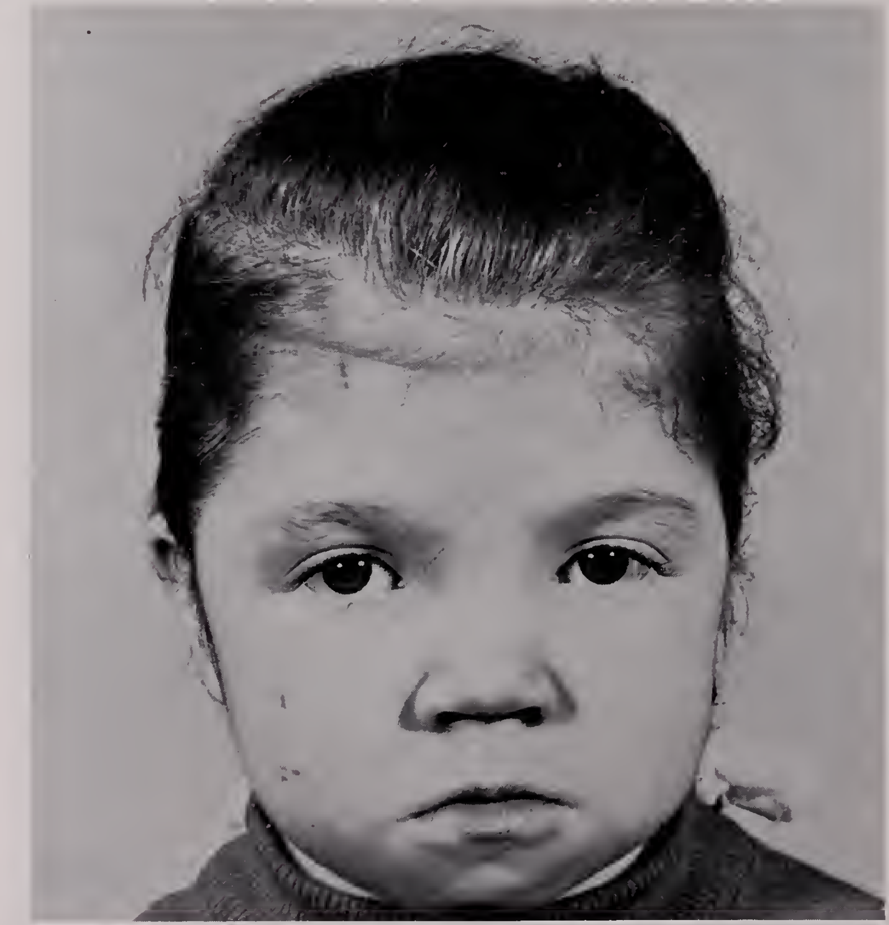

Fig. 1 — Acquired hypothyroidism with apathic facies and low hair line.

*Teacher, Robbinsdale Public Schools.

**Senior Medical Student, Comprehensive Clinic Program, University of Minnesota Medical School.

speech and "very quiet." The patient has always been a poor eater and has been constipated throughout her life. The mother has also noted that her hair and skin have been rather coarse compared with those of the other children in the family.

Physical Examination

Examination showed a pale, very shy, apprehensive female who was small for her age. Her height was 93.5 cm. and her weight, 15.6 kg., both of which were far below the third percentile. Her hair was very coarse and extended down over her forehead, and a flattened nasal bridge was noted.

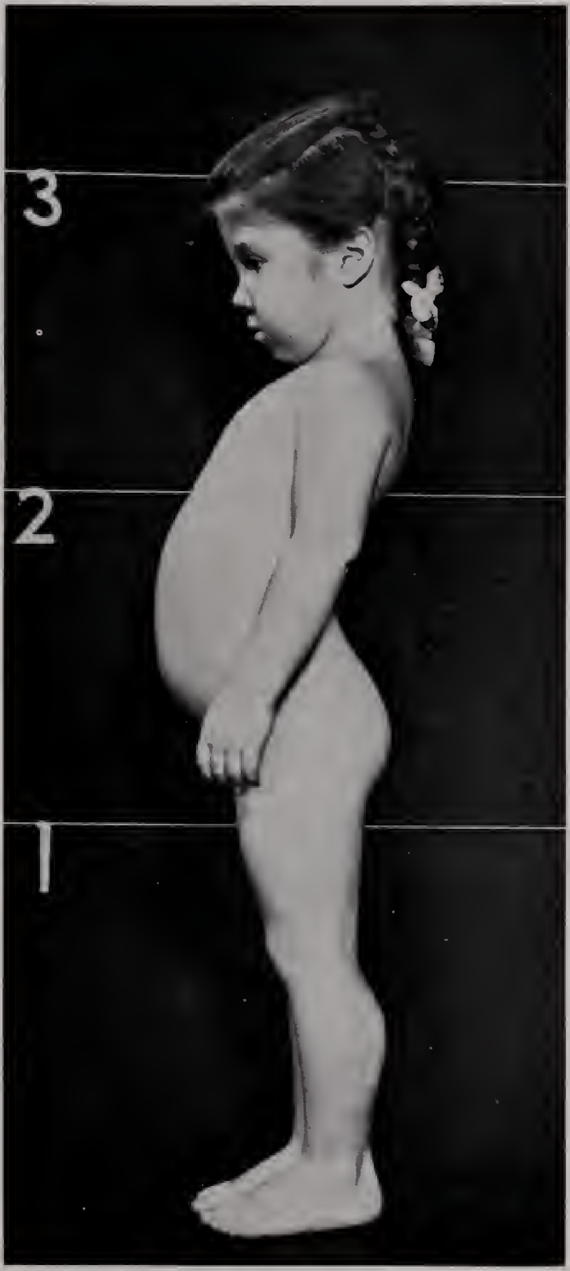

Fig. 2 — Acquired hypothyroidism. Note protuberant abdomen, flattened nasal bridge, and increased hair on arms and back.

Continued

The thyroid gland was not palpable. Her skin was very dry and there was dark, coarse hair on her arms. A grade I/IV heart murmur was heard, interpreted as functional in nature. Her liver was palpated 2½ cm. below the right costal margin and no spleen was felt. The neurological examination showed a very slow response in the deep tendon reflexes. Mental examination was difficult because of her shy, withdrawn nature.

She was admitted to the University of Minnesota Hospitals in February, 1965, for further thyroid evaluation, after protein-bound-iodine of 2.3 mg. per cent was obtained. Other studies in the hospital showed a T_3 of 8.9 micrograms% (10-14 micrograms%, normal range); radioactive iodine uptake of 5.7% (normal — 20-40%), and a bone survey consistent with hypothyroidism. Her serum carotene was 208 mg.%; vitamin A, 35 mg.%; serum cholesterol, 282 mg.%, and hemoglobin 11.8 grams%. A thyroid scan showed a sublingual thyroid gland.

A muscle biopsy was performed which was histologically normal. Electromyography showed a pattern consistent with myopathy, affecting proximal as well as distal musculature.

Dr. Richard Chilgren*

A diagnosis of acquired hypothyroidism was considered. Her weight chart shows that she was in the 50th percentile until two years of age; at that time her weight leveled off and has shown essentially no increase (Figure 3), which indicates that she does not have complete absence of thyroid. To further establish this fact, the thyroid scan was performed and showed a picture of the lingual thyroid, which is quite rare. Dr. Henning Anderson of Sweden feels that this condition is more common than previously thought, because the linguinal area is usually not included in the thyroid scan. Embryologically,[1] the thyroid has its origin at the base

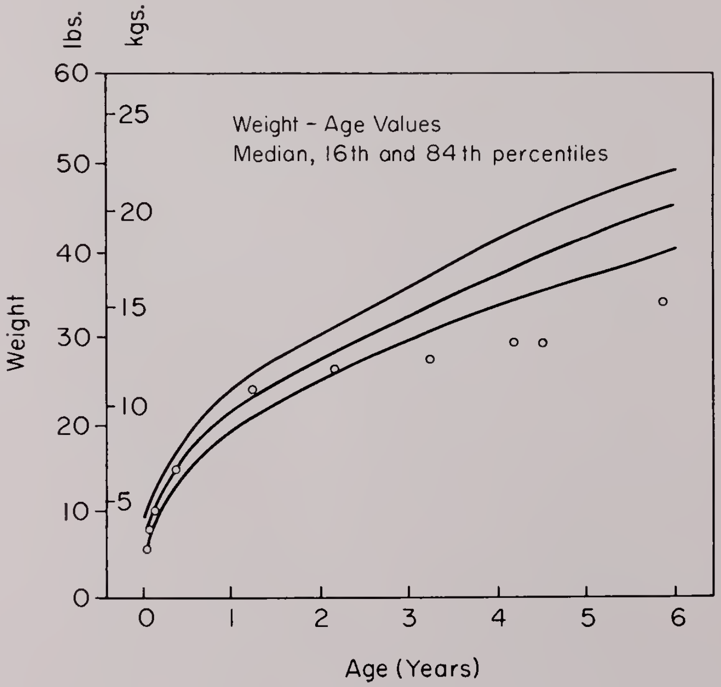

Fig. 3 — Weight chart of patient with acquired hypothyroidism, showing fall-off at 1-2 years of age.

---

*Pediatric Metabolic Resident, University of Minnesota Medical Center.

of the tongue and then migrates to a position in the anterior portion of the neck in front of the trachea. When the gland does not migrate and stays in the sublinguinal area, it functions for a while and then stops after one to two years. Thus, this condition is different from cretinism, in which children are born with no thyroid. Her bone age at the present time is less than that of a one-year-old child and her height and weight correspond to those of a three-year-old child. This is also consistent with a diagnosis of acquired hypothyroidism.

Treatment

Presently she is being treated with desiccated thyroid, starting at a very low dose of ½ grain, which will be gradually increased by ¼ grain each week, to 2 to 4 grains eventually. The end point of therapy will arrive when the protein-bound-iodine enters the range of 5.5 to 7 mg.% and when she shows a clinical response. Hopefully, her intelligence will increase, but this has not been assured to the parents. Usually the prognosis is good in this condition; we expect a longer growth phase and she should approach normal height, though there may be some doubt that she will completely attain it.

There was no evidence of any adrenal or pituitary dysfunction and her electrolytes were normal. A thyroid-stimulating-hormone test would not change the therapy and, as with the SU 4885 test, was not felt to be indicated. Thyroid-stimulating-hormone for treatment is an interesting idea but desiccated thyroid remains the desired treatment.

The toxic signs of the medication that would be helpful to alert the school officials are: (1) severe agitation and irritability which may occasionally, but rarely, result in unconsciousness and seizure manifestations; (2) ravishing hunger; (3) profuse sweating, and (4) rapid heartbeat. If any of these signs are observed in the patient, Dr. Rotenberg should be contacted.

Dr. Robert ten Bensel:

Chronic normochromic, normocytic anemia is a not uncommon finding in acquired hypothyroidism and is unresponsive to iron. The nature of this anemia is not known; but thyroid is probably important in red-cell metabolism.

Mrs. Mary Cordingley:*

Both the mother, age 34, and the father, age 38, are slow-moving, slow-speaking, and rather passive in attitude. The father is a foreman of a potato-processing plant. Upon his recent return to his company he was unable to get group insurance because of the patient.

Other children in the family include a fifteen-year-old boy and twins, thirteen years old. Although there have been no special behavior problems in school, one of the twins has some academic difficulties and tests in the low-normal range. The oldest of the boys is doing extremely well. Their attitude toward the patient is one of solicitude.

Perhaps in visualizing the patient's potentials, one should not ignore the slow, passive attitudes of the parents and the limited ability of the low-normal twin. Such familial patterns may serve as limitations to the patient.

Heretofore, most of the plans made by these parents have been results of suggestions by others, indicating their basic trust and willingness to

---

*Social Worker, University of Minnesota Medical Center.

Continued

co-operate. It is therefore important that these parents have an exact interpretation of the expected progress and an evaluation of possible changes in their child's development. Because of their literal interpretations and high expectations of improvement, these parents may be likely to expect more than is physically possible; therefore idealistic projections should be kept to a minimum.

Dr. Paul Moe:*

In examining the patient the most striking finding was her mental torpor. She had very little concept of numbers but could count to five. She knew simple body parts; but in general her mental ability was judged to be at an 18 to 24-month level. On neurological examination the only abnormal finding was her "hung up" reflexes.

Mental Development

The nervous system is often affected in hypothyroidism, and affliction may express itself in a variety of ways.[4] In adults, paresthesias, ataxia, headaches, seizures and hearing deficits are observed. The adult usually retains his intellect, whereas the infant may show severe impairment, especially when there is congenital absence of the thyroid gland. The question from the neurological point of view is: how adequately will her intelligence develop. Wilkins[3] feels that in acquired hypothyroidism 40% of the children will have an I.Q. greater than 90 and 6% will have an I.Q. of less than 50. Williams[2] feels that of children who have acquired hypothyroidism with onset between one and two years of age, approximately 90% will reach an I.Q. in the normal range. It is important to remember that the most meaningful evaluation of this child's intelligence will be approximately two years after treatment has been started. Early, there may be scatter in the intelligence testing, due to psychological reactions to therapy.

Myelination of Nervous System

In the child who is born without a thyroid gland it has been shown that thyroid is important in myelination of the nervous system, impaired at birth. Myelination is usually completed in the first 24 months of life; therefore this child should have little permanent intellectual impairment. In general, her prognosis should be relatively good and she should achieve well.

Dr. Harold Ireton**

The child was found to be almost totally nonverbal. Responses were indicated by shaking her head and by performance on nonverbal test items. At the time of testing she was six years, four months old. On the Binet nonverbal tests she demonstrated a mental age somewhat under five years (M.A., 4-8, estimated I.Q., 70). She showed some tendency to perseverate† on this test. On the Draw-A-Man Test, she performed on approximately the same level (M.A., 5-0), but her drawing included unusual distortions (the body was drawn within the outline first drawn as a circle for the head). On the Peabody Picture Vocabulary Tests, her performance was considerably more retarded (M.A., 3-1, I.Q., about 50). The results of testing, especially her limited vocabulary, indicated general mental retardation. Her limited language use is probably a reflection of such retardation rather than of "shyness." The mother's report on the patient's general social adjustment (Vineland Social Maturity Scale) indicated approximately average functioning for her age, except in the area of communication; but her report may be somewhat exaggerated.

†See Test Your Word Score Page 1167.

Both parents recognize her speech limitations, but the father appears relatively more aware of the degree of her intellectual limitation. Neither parent shows any significant psychiatric disturbance; but the father seems to be quite introverted, a lethargic type of person, who is probably chronically somewhat depressed. Unless there is significant change in the rate of mental growth, the child's education should continue at a slowed pace, geared to her mental age with special class education. At the present time, specific remedial reading or similar therapy does not seem indicated. Even though there is medical optimism about the reversibility of her general condition, this should not be communicated to the parents. Failure of intellectual improvement under such expectations could be psychologically damaging to the parents and interfere with meeting the child's present needs.

Final Recommendations of the Conference

1. Dr. Rotenberg will maintain his role for the primary medical responsibility in this case.
2. The patient will be seen in the Endocrine Clinic on a weekly basis until her thyroid medications are adequately adjusted. She will then be seen at one to six-month intervals for a period of time, and then yearly to judge the effect of therapy.
3. Close communication will be maintained between the University Hospital, Dr. Rotenberg and the school, regarding progress and changes in her condition.
4. Psychological testing should be performed by the school in approximately two years in order to re-evaluate her educational situation at that time.
5. It was generally agreed upon that counseling of the parents should maintain a positive attitude, but one should move slowly in prognosticating her eventual intellectual status.

Child Psychiatry

The Child and the Physician*

Children epitomize the concept that tomorrow is today. We who work with children — and most of us do unless we are internists or geriatrists — have a share in molding that tomorrow. It is a challenging responsibility. In this — the first of the series — we will discuss some of the real differences between the practice of medicine with adults and with children. Perhaps because the differences are so simple, they are often overlooked.

Physician-Patient Relationship

In the practice of medicine with adults, the physician-patient relationship is usually on a one-to-one basis. True, the physician may include members of the family in his management of the patient, but essentially he deals directly with the patient. It is quite different in the case of a child. Here the physician invariably is dealing with a situation in which two or more individuals are involved. He tries to determine as quickly as possible what the pertinent factors in the complaint are. Usually it is the parent — not the child — who gives the complaint. The latter, particularly if he is an older child, should be encouraged more often to tell his own story. Three possibilities must be considered:

1. There may be something wrong with the *child*. Does he have an infection, a malignancy, or a deficiency of some type?
2. The parent may be bringing the child as an "admission ticket" when actually he wants help in understanding and managing the child. In other words, is the *parent* seeking counsel and guidance?
3. *Both* the parent and child may need assistance in resolving a stubborn, unhappy interpersonal relationship.

None of the three possibilities emerges in pure culture, because the parent-child relationship is so intimate. To illustrate, a child may require an operation. At the same time, parental concerns about the child's welfare must also be recognized and relieved. The physician's failure to do so can further complicate an already difficult situation. Similarly, though the parent may himself be seeking help, the child should be carefully examined. If a troublesome interpersonal relationship seems to be the main problem, recognition of the accompanying stress for both parties offers many opportunities for amelioration.

Patient Motivation

The adult comes to the physician for relief of his suffering. Central to it may be a physical disorder, an emotional problem, a feeling that he is a failure or that the difficulties of living are overwhelming. The adult manifests his confidence in the physician by *coming* to him. The child, on the other hand, is *brought* to the physician by a parent or parental surrogate.* The doctor may be the last person the child wishes to see;

*See Test Your Word Score Page 1167.

Continued

chances are his training, knowledge, skill, or erudition will 'cut little ice.' The child is interested in what kind of person he is. Does he like and understand children? Can he be trusted? No matter how gracious or smooth his professional demeanor may be, he cannot hide behind it. The child knows intuitively what he is.

The case of Daniel, aged six, illustrates this point. During the first visit the physician was most condescending in his speech and manner. Daniel tolerated the procedures until the time arrived for auscultation of the heart and chest. The physician, trying to ease his patient's discomfort, said soberly, "Now Danny, my little man, let me listen through this telephone." That was too much! "Doctor," Danny shot back, "some people call that a stethoscope." The physician suddenly realized he had better change his approach.

Communication

The physician uses different avenues of communication with children than with adults. Nonverbal systems predominate with the infant and the toddler. Plant states it this way: "Our rich and adequate contacts with young children are through the psychomotor tensions." Messages are carried by how we hold a child, turn him over, auscultate and percuss. Facial expression, eye movements, tone of voice, cadence, and timbre are important — particularly when the child is a little older; but too often we forget about these factors.

Most children begin to formulate sentences between the ages of 18 to 24 months. At five or six years the average youngster has a working vocabulary of several thousand words. By this time verbal communication supplements though never entirely supplants nonverbal communication. Words, however, do not always convey the intended meaning; they can be traps as well as useful tools, even between adults. The physician dealing with children must make doubly sure that the child actually understands what he says, and that he understands what the child tells him.

Attitude Toward Child's Problems

The problems of adults are taken seriously; at least, we give them a fair hearing. But too frequently we regard children as "little people with little problems." We need to remind ourselves that every human being is engaged in the struggle to master successfully the problems of his own everyday life, the fight to maintain a sense of dignity and balance. This is true whether the individual's age is one month or five years or 10 or 20 or 50 years. Actually, the child's struggle may be more intense than the adult's, because his dependency on others sometimes increases tensions to the point where his frustration tolerance is threatened. If we are to appreciate fully the child's need to maintain a sense of his own worth, we must accept the simple fact that he — like everyone else, regardless of age — has problems of life adjustment which can undermine his self-confidence and security, problems which look big to him.

Roles of Physician

The roles we assume as physicians dealing with children and their parents may be different from those we assume in dealing with adults.

---

*See Test Your Word Score Page 1167.

For the child, we temporarily become a substitute parent; for the parents, we stand in the symbolic role of a parent. Fulfilling these roles and being mindful of their implications require each of us to examine our own attitudes, not only toward the children and parents, but toward ourselves and our procedures. The manner of our approach unquestionably reflects our basic orientation.

Parents usually are full of questions; we must be careful not to close the door on them. They expect us to counsel them in matters concerning their children's emotional and social development as well as in their eating, sleeping, and toilet training programs. Counseling, as distinguished from giving direct advice, means that we think a problem through *with* the parents, give them information, perhaps offer alternative courses of action for their consideration: in other words, that we help *them* make a decision rather than make it for them. This approach increases the chances for success because the parents presumably are ready to take the action agreed upon. If it fails, however, they tend to be more willing to try another tack instead of shrugging their shoulders and muttering, "The doctor doesn't know what he's talking about." This is not to say direct advice should never be given. Circumstances may demand it. But the manner in which it is given must be tailored to the circumstances and the individuals involved.

Preparation for Initial Visit

It is important for the physician dealing with children to ascertain what kind of preparation the child received before his first visit. A 12-year-old boy who was brought to a child psychiatrist is a case in point. It was unusually difficult to establish a friendly relationship with him. Every gesture the physician made was firmly and definitely rebuffed. Eventually the child became very restless. Noting the lad's increasing discomfiture, the psychiatrist said, "Something seems to be troubling you. Tell me about it." Hesitantly the child asked, "When are you going to look at my teeth? My mother told me I was coming to see a dentist." No wonder both doctor and child were floundering!

Direct

Direct preparation of the child by the parent is better now, on the whole, than it was years ago; however, there is no guarantee. Occasionally parents still use us doctors as a threat: "What will happen to you if I have to take you to the doctor?" they ask. This presents an unnecessary additional hurdle. If we are on the alert for opportunities, we can help parents do a better job.

Indirect

The indirect preparation a child receives may be even more unsettling and significant. Casual comments of parents or relatives about their own particular experiences with a physician; or, more maliciously, hair-raising tales of other children about their adventures with doctors and hospitals may get us off to a poor start. Phantasy is stimulated; questions are raised but not answered. The result may be an extremely anxious patient. In all probability our difficulties with some children are due in part to adverse

Continued

conditioning. An awareness of this possibility may help us win the confidence of the child. Once we have done that, is it not true that he will cooperate with us in the most trying, difficult procedures?

Reynold A. Jensen, M.D.
Minneapolis, Minnesota

Anglo-Saxon Leechdoms for Worms*

Against a hand worm, take ship tar, and sulphur, and pepper and white salt, mingle them together, smear therewith.

If a worm eat the hand: take marsh maregall, red nettle, red dock, and the small bur, boil in cows' butter; when the salve is sodden, then further take of salt three parts, shed thereupon, shake together and smear therewith; lather with soap, about night-time smear therewith.

Against a deaw worm (foot worm), let the man step upon a hot coal; let him cool (his foot) with water, let him step upon it, as hot as he hottest may.

For a deaw worm, some take warm thin ordure of man; they bind it on for the space of a night. Some take a swine's lung warm.

If the ana worm (bot) grow in a man smear with the black salve. If the worm eat through to the outside and make a hole, take a drop of honey, drop it on the hole, then have broken glass ready ground, shed it on the hole; then as soon as the worm tastes of this he will die. A salve against the ana worm thus shall one work; take cinquefoil, that is five leaf, and rue, boil them in butter, sweeten with honey.**

---

*The generic term 'worm' probably included all very small marauders on man: worms, insects, pediculi, mites, fungi, etc.

**Payne, Joseph F., M.D. Oxon.: English Medicine in the Anglo-Saxon Times, Oxford at the Clarendon Press, 1904, p. 44-46.

Adoptive Parents Needed

Because of the increasing number and rate of illegitimate births, the number of children in need of adoptive homes has increased by geometric proportions in the past few years. For example, the Children's Home Society of Minnesota, 2230 Como Avenue, St. Paul, a state-wide nondenominational adoption agency, accepted and placed 100 children in 1953. In 1963, this Society placed 227 children and in 1964, 245 children; and still the agency can accept fewer than half the number of children referred to it.

Today the Children's Home Society of Minnesota, a United Fund agency, has one couple for every child in its care. However, with the ever-increasing number of children that are becoming available for adoption, it is necessary that the number of couples seeking children must also increase. Adoption procedures have gone through a great transformation since the Children's Home Society of Minnesota was organized in 1889, and therefore, the Society encourages couples and families to consider the adoption of a child or an additional child. The Society has no limit as to number of children placed with any one family. As long as there is reasonable financial security and ability to meet the basic needs of an additional family member, an application will be encouraged.

Grand Rounds

Dermatomyositis*

Dermatomyositis is a disease of multiform nature, usually associated with cutaneous lesions, extensive muscle weakness and muscle tenderness.

In 1887 Wagner described a 34-year-old female with painful muscles and joints and weakness of the shoulder girdle, who died a few weeks after she was first seen. This was one of the first clinical descriptions of acute dermatomyositis. Oppenheim was the first to emphasize the similarity of dermatomyositis and progressive scleroderma. In 1905 Steiner reported one of the first cases recognized in America.

Polymyositis hemorrhagica, dermatomucomyositis, neuromyositis, dermatoneuromyositis and angiomyositis are terms formerly used to designate dermatomyositis.

Incidence

Dermatomyositis has been found to be most frequent in the fourth and fifth decades of life with the age range between 20 and 69 years.[1,4,5] The disease was fatal in 40% of one group of cases. It is more common among females.[3]

Etiology and Pathogenesis

The etiology of the disease is not known. Bacteria, including streptococci and staphylococci, viruses and parasites have been implicated in an attempt to explain the pathogenesis. Wedgewood et al. measured the serum antistreptolysin titer in seven patients during the acute phase of the disease and found no elevation.

Hypersensitivity to toxins, drugs, especially the sulfonamide compounds and penicillin, sunlight and other agents have been suggested as causal.

Curtis and co-workers[1] reported that 7-15% of adult patients with dermatomyositis have associated carcinoma. In one series of 23 patients over 40 years of age, 12 (52.2%) had associated malignant disease[2] which may elaborate antigen to which the body responds with antibodies.[1]

---

*Presented as a Medical Grand Rounds at Mt. Sinai Hospital, Minneapolis, February 23, 1965.

Continued

Immunoelectrophoretic studies have shown that in patients with dermatomyositis and lupus erythematosus, there is an increase in the alpha beta and gamma globulins. Also identified in dermatomyositis and scleroderma are gamma globulins which react with cell nuclei. Antinuclear fluorescence has been found in patients with rheumatoid arthritis, scleroderma and dermatomyositis.

Pathology

O'Leary and Waisman reported that the initial pathologic reaction involves plasma cells, histiocytes, fibroblasts and mast cells. Precapillary arterioles and venules may show thickening of their walls. Collagen deposits, localized areas of necrosis, cellular infiltration and increased vascularity extend into the subcutaneous spaces. Whether the subcutaneous tissue is affected by direct extension from the skin peripherally, or the muscles centrally, has not been determined.

The heart muscle may show swelling and early pyknosis of the nuclei of individual fibers. In isolated instances, nonbacterial endocarditis and pericarditis have been observed.

Ulcers of the esophagus, stomach, portions of the small bowel and rectum have been described. The ulcerations have been associated with edema and cellular infiltration of the walls of the arteries and veins. Subsequent stages of this process lead to mucoid and fibrous thickening of the intima, with narrowing of the lumen and thrombosis.

The kidney is particularly susceptible to extensive vascular changes. One patient with dermatomyositis seen early during the course of her disease developed generalized calcinosis with skin changes that suggested scleroderma. Pathologic examination of the kidneys showed endarteritis of the interlobular arteries.

Wedgewood et al. consider the vascular lesions in dermatomyositis more difficult to distinguish from those of thrombotic thrombocytopenic purpura but unlike those of polyarteritis, in that necrosis and inflammation of the vessel wall are minimal or absent.

Clinical Findings

The disease may begin insidiously with a low-grade fever, malaise, minimal aches and pains of the extremities, and without any significant antecedent illness. Twenty-four per cent (24%) of cases reported by Sheard had sudden onset; 32% complained of edema or a rash on the face as a presenting symptom.

Cutaneous Manifestations

Some patients may suffer an acute viral or bacterial infection at the onset of the illness; cutaneous manifestations in some patients precede symptoms of muscle involvement.

Erythema may be present with or without subcutaneous edema and may be mottled or diffuse, livid or rosy. The term "heliotrope" has been applied to the appearance of the affected eyelids. The face and the anterior neck are common sites of the erythema, followed in frequency by involvement of the extensor surfaces of the arms, the legs and the trunk. When edema is present, it may be pitting, brawny or indurated. Purpura, vesicles and bullous formation have been reported.

During the natural course of the disease, the cutaneous manifestations undergo alteration; pigmentation, atrophy and telangiectasia may predominate at a later stage. These changes may be sharply demarcated from normal skin on the exposed portions of the body. The similarity to the dermatitis of pellagra, the pigmentation of adrenal insufficiency or localized morphea may confuse the presumptive clinical diagnosis. Wedgewood noted erythematous, atrophic and scaly lesions in children, with a network of fine blood vessels visible over the extensor surfaces of the joints, particularly the knuckles, elbows and knees. Partial alopecia has been reported in several patients.

Muscular Manifestations

Muscular weakness, aching and fatigue may be a prominent or an insignificant clinical feature. Any striated muscle may be affected, although there is a tendency for the development of bilaterally symmetric lesions. The large muscle masses are more likely to be involved than the pharyngeal, laryngeal, intercostal, diaphragmatic or ocular groups. The proximal muscle groups of the upper and lower extremities are more likely to be involved than the distal goups.

A majority of patients have diffuse muscle tenderness. Extensive involvement upon microscopic examination has been found in muscles that have been neither painful nor tender on palpation. The consistency of involved muscles may be normal, doughy, firm or fibrous. Weakness of facial and glossal muscles makes eating and speaking difficult. Extensive involvement of the muscles of respiration and deglutition may occur. Muscle atrophy is common, and extensive fibrosis with contractures of the elbows, knees, hips and fingers develops if the disease progresses to a subacute and chronic phase.

Ocular Changes

Lisman has described in detail the ocular changes in one patient with dermatomyositis and compared his findings with a similar case reported by Bruce. The patient, a 53-year-old male, had suffered generalized weakness for approximately six months. His eyelids were swollen and the surrounding skin was pink from telangiectasia. The edematous area of infiltration pitted upon pressure. The lower lids hung in folds and were tender to touch, attributed to involvement of the orbicularis oculi. Post-mortem examination showed hyaline and lipid changes in the external plexiform layer of the eye, especially around the macula, and a few scattered hemorrhages in the retina. The vessels showed no pathologic changes.

Other Changes

The bronchi and lungs may be involved and symptoms of cardiac dysfunction have also been observed.

Involvement of the gastrointestinal tract may produce symptoms that are indistinguishable from those of systemic scleroderma. These include stomatitis, myositis of the tongue, dysphagia and epigastric distress. Splenomegaly and lymphadenopathy may be present.

Central and peripheral nervous systems may be affected, with resulting confusion, psychosis, delirium, diminished tendon reflexes, hyperesthesia, numbness of the hands and feet, and foot drop.

Continued

The association of dermatomyositis with myasthenia gravis or with thyrotoxic myopathy has been discussed by Ragan and Dawling. The muscle weakness of myasthenia gravis or severe thyrotoxicosis bears a casual similarity to that of dermatomyositis. Microscopic examination of the affected muscles reveals selected pathologic changes common to each illness.

Diagnosis

The disease may be suspected in patients with atypical rheumatoid arthritis or with acute rheumatic fever, who do not respond to therapy. Muscle weakness or tenderness, particularly of the shoulder girdle and upper arms, together with skin lesions, fever and malaise, should suggest the possibility of acute dermatomyositis. Inquiry should be made regarding a previous history of Raynaud's syndrome or of presenting complaints of facial or periorbital edema. Pathologic changes in muscle and skin lesions from biopsy material are helpful in diagnosing the mild or early case. However, a negative biopsy in a patient with clinical evidence of dermatomyositis does not exclude the diagnosis. The severity of the myositis is related to the clinical severity of the illness. Early in the course of the disease it may be difficult to distinguish this disorder from the edematous stage of scleroderma* or scleredema.

Clinical Course

In most instances the disease is considered fatal. The clinical findings usually become progressively worse. More than 50% of the patients with the acute fulminating type die without a demonstrable remission. Death within eight weeks from the onset of symptoms has been reported. The average expectancy under current therapy in patients without a malignant tumor is approximately three years from the onset of clinical symptoms. Survival may be prolonged for a decade or more if the disease becomes partially quiescent and regresses into the subacute or chronic stage. Remissions with apparent restoration of health have been observed to occur spontaneously, induced by steroid therapy and following removal of an associated malignant tumor. Death from intercurrent infection, cardiac failure or renal insufficinecy may be expected in the acute fulminating type.

The series of Talbott et al., recently brought up-to-date, shows only two patients alive and in remission. One, a 51-year-old female, has experienced a remission for more than 18 months, thought to be associated with adrenal steroid therapy.

Cause of death before the antibiotic era was due to overwhelming infection. Cardiac failure from myocarditis may lead to death, as may pulmonary insufficiency caused by progressive fibrosis.

Laboratory Findings

Blood studies may show an elevated white count with a relative lymphopenia and polymorphonucleosis and occasionally an eosinophilia as high as 25%. Sedimentation rate may be elevated out of proportion to the constitutional symptoms.

During the active stages of muscular weakness transaminase is released from damaged skeletal muscle fibers into the peripheral blood; its determination provides a valuable clue as to the continued progression of muscle necrosis. As recovery begins, the enzyme levels return to normal.

---

*See Test Your Word Score Page 1167.

In eight cases reported by Pearson, seven had elevated levels of serum glutamic oxaloacetic transaminase. The lupus erythematosus clot test is negative. Slight increase in gamma globulin has been observed. There has been no characteristic alteration in the electrolyte pattern.

An electrocardiogram may show changes suggestive of interstitial fibrosis of the myocardium. The alteration consists of prolongation of P-R, QRS and Q-T intervals, minimal variations in the appearance of RS-T segments and T waves, as well as slurring and notching of QRS deflections in multiple leads.

X-ray Findings

When dysphagia is a complaint, roentgenographic study of the swallowing mechanism may reveal weakness of the pharyngeal musculature and pooling of barium in the pyriform sinuses and valleculae.* Fluoroscopic examination of the chest may show diminished expansion of the lungs and reduced excursion of the diaphragm. X-ray study may reveal interstitial infiltration or diffuse fibrosis. Examination of the soft tissues in chronic cases may show extensive subcutaneous calcification and osteoporosis. Calcium deposits occur along fascial planes such as in the axillae and the plantar surfaces of the feet, as well as in the subcutaneous areas along the extensor surfaces of the forearms and in the subcutaneous spaces of the fingers, toes and buttocks.

Electromyogram

Electromyography reveals action potentials of short duration which may be polyphasic and reduced in size, with little or no reduction in the total number of motor unit discharges on voluntary contraction. Spontaneous fibrillations are recorded in the active phase.

Treatment

Until the advent of steroid therapy the treatment of dermatomyositis had been ineffective.

Steroids suppress the inflammatory reaction in the muscles, and with adequate dosage the patient becomes more comfortable, complications are reduced, and the extent of residual crippling is lessened considerably. Few patients, especially children, escape without residual disability. The possibility of relapse must always be anticipated. The length of time steroids should be continued has not been established. Treatment courses lasting for six to 18 months are not unusual.

Antimalarial drugs and anabolic agents such as testosterone or norethandrolone have been tried, but benefit is questionable.

Supportive therapy should include prophylaxis against intercurrent infections. These patients are particularly vulnerable to respiratory infections. Contracture cannot be avoided, but it can be kept to a minimum by heat and splinting. Physical therapy to keep the joints and muscles supple may be introduced after the acute phase subsides. Activity should be restricted.

Case Summary

A 14-year-old white female had appearance of edema of the eyelids in March, 1964. There had been no preceding febrile illness, allergy, medication or dietary indiscretion.

Continued

At the start there was some improvement of the lid swelling with antihistamine; but soon the swelling became fixed and so marked that it interfered with her vision. She was first hospitalized in May, 1964, and treated with prednisolone. About two weeks prior to that hospital admission she had developed muscle aching and soreness, mostly in the upper arms, shoulder girdles and lower back. There was no disturbance in gait, tremor or fasciculation noted.

In November, 1964, she developed pain in the left neck with diffuse hard swelling which gradually subsided. She was able to continue her schooling and to participate in the farm work and household chores despite awareness of increasing fatigability and progressing weakness on exertion. Family history and system review were negative.

On November 20, 1964, she was admitted to Mount Sinai Hospital for the first time.

Physical examination on admission revealed a well developed, well nourished female. The most striking finding was the presence of tense edema of the eyelids with a purplish-reddish hue. Near the inner canthus of the right eye the skin was shiny. There were no conjunctival abnormalities. The remainder of the examination was entirely negative except for a noticeable weakness of the sternocleidomastoid muscles and also the muscles of the shoulder girdle, particularly on the left. Neurological examination showed a generalized hyporeflexia of the deep tendon reflexes bilaterally. Cranial nerves were normal.

Laboratory Findings

Laboratory examination revealed the following. Urinalysis showed specific gravity of 1.020, pH 6, 50-70 rbc and 5-8 wbc. Hemoglobin was 13.3 gm% and hematocrit 43%. White blood count was 5,100 with 53% neutrophiles, 38% lymphocytes and 9% eosinophiles. Serum chlorides 105 meq/L, Na 141 meq/L, potassium 4.5 meq/L, calcium 9.1 mg%. Platelet count 230,000. Bleeding time 3.3 min. Prothrombin time 12.9 sec. Phosphorous 5.8 mg%. Venereal disease research laboratory test for syphilis negative. Blood urea nitrogen 21 mg%. Sedimentation rate 28 mm. in 1 hour. Serum transaminase was 178 and 140. Uric acid was 6.8 mg%.

Muscle biopsy revealed moderately extensive degenerative changes in the skeletal muscle fibers with vacuolization and hemogenization of sarcoplasm. Scattered myofibers were fragmented and hyalinized and appeared to show partial phagocytosis. Occasional small muscle groups were largely atrophic and showed partial replacement by fibrous tissue. The changes were consistent with those occurring in progressive dermatomyositis. Electromyographic studies revealed myopathy involving the proximal muscle most severely.

Treatment and Course

In May, 1964, she was first treated with adrenal cortical steroids and kept at bed rest. During the summer months her muscle pain subsided, but she began to have progressive weakness of the muscles of the left shoulder and biceps. There was a noticeable change in the quality of her voice which became more nasal. She also had regurgitation and difficulty in swallowing liquids. Her diet was somewhat limited, but no marked weight loss occurred. The steroid dosage was gradually reduced, and by late July, 1964, she was able to resume partial activity. A program of physical rehabilitation was begun. In August, 1964, she was considerably stronger and the steroids were discontinued. She was allowed to go back to school, but in October, 1964, renewed activity appeared with facial erythema and edema and aching of the muscles of the shoulders, neck and back.

Prednisolone therapy was again started and, in addition, sodium salicylate was given. On admission to Mount Sinai because of progression of symptoms the prednisolone dosage was increased to 48 mg. per day. Besides prednisolone she was also receiving 90 grains of aspirin daily.

In January, 1965, her case was presented to the University Dermatology Conference, and it was suggested that high dosage of steroids be continued. Despite this therapy her muscle pain and weakness became progressively worse, and she began to have persistent regurgitation of liquids through the nose and contractures of the left arm and right leg.

On February 18, 1965, she was transferred to the University of Minnesota Hospital.

Advances

Antidepressant Drugs

Review and Application*

JAMES JANECEK, M.D.**
Minneapolis, Minnesota

ENCOURAGING A depressed patient to swallow something is not a recent innovation. Alcohol has been used for thousands of years to alleviate the melancholy moment. Opiates and barbiturates, and more recently, amphetamines, have been used in depressive illnesses; but only within the last decade have antidepressant agents without intoxicating and habit-forming properties been available. These newer substances are both touted as panaceas for the miserable and disparaged as the profitable promotions of their manufacturers. Such debates are not new in medicine, and only time will prove whether these agents are really valuable. Nevertheless, these drugs are in wide use, and their careful consideration is warranted.

Depression is hard to define, to describe, and to classify. The term may designate a *symptom* when used to describe a feeling state associated with many illnesses and situations; or it may designate a *syndrome* (a collection of symptoms) such as neurotic depressive reaction. Rarely has it been used to mean *disease*, such as manic-depressive disease, which would imply a specific etiology.[1] In general, drugs used in psychiatry are symptomatic (nonetiological) therapies. Simple sadness or crying is not usually an indication for an antidepressant drug. One difficulty in assessing the literature of these therapies is the difficulty in determining what was treated — symptom or syndrome? As a symptom, depression is common to all men, but it is also extremely transient and likely to abate spontaneously. As a syndrome, depression is also common, and while both spontaneous and placebo remission rates are high, therapy can be crucial. Further complicating the assessment of antidepressant drugs is the availability of a proven therapy, electroshock. Some controlled evaluations of antidepressants have used for subjects patients with poor prognoses who may not have responded to electroshock or other therapies. All told, the problems posed by indications, spontaneous remission, placebo response, availability of electroshock, and the kinds of subjects used in some studies have resulted in a mass of contradictory reports.[2]

Why, then, use drugs? The reasons are few and simple. First, drugs can be used by all physicians. Second, antidepressant agents do not interfere with daily functioning, and patients, if helped, prefer them to electroshock.[3] Finally, desire for a prescription can bring a patient to the physician's office for necessary psychological support and direction. Patients generally expect tangible treatments, and the popularity of antidepressant drugs depends, in part, on this

**Assistant professor, Department of Psychiatry & Neurology, University of Minnesota.

expectation. Fulfilling the expectation need not be defended, but it should not be encouraged. Despite their limitations, antidepressant agents used judiciously and knowledgeably with other medical treatments can prevent many disasters.

Psychiatric Drugs

Benson and Schiele[4] have classified psychotropic drugs as major tranquilizers, minor tranquilizers, and antidepressants; Table 1 is an adaptation of their classification. Drugs used in depressions can be classified on the basis of pharmacodynamic activity.

Central Nervous System Direct Stimulants — the Amphetamines

Although they provide immediate euphoriant effects, the amphetamines are minimally useful in treating classic depressive syndromes; however, rapid development of tolerance and the danger of habituation or general abuse limit their use. They sometimes help counteract sedation induced by anticonvulsants and other sedatives and, on occasion, are helpful in grief reactions; but they are contraindicated in alcoholism or any addiction, and in the triad of passivity, obesity, and fatigue common to certain depressive conditions. Table 1 lists the two most potent and habit-forming amphetamines first and the three least potent and habit-forming last.

Indirect Stimulants — the Monoamine-Oxidase Inhibitors

TABLE 1

Drugs Used in Depressive Syndromes

- A. Central Nervous System Stimulants
  - 1. Predominantly Direct Stimulants
    - a. Amphetamine (Benzedrine)
    - b. Dextroamphetamine (Dexedrine) (Biphetamine)
    - c. Methamphetamine (Desoxyn) (Ambar Tablets)
    - d. Pipradrol (Meratran)
    - e. Methylphenidate (Ritalin)
  - 2. Indirect Stimulants
    - a. Isocarboxazid (Marplan)
    - b. Phenelzine (Nardil)
    - c. Nialamide (Niamid)
    - d. Pargyline (Eutonyl)
  - 3. Bimodal Stimulants
    - a. Tranylcypromine (Parnate)
- B. Central Nervous System Suppressants
  - 1. Imipramine (Tofranil)
  - 2. Amitriptyline (Elavil)
  - 3. Desipramine (Pertofrane) (Norpramin)
  - 4. Nortriptyline (Aventyl)
- C. Miscellaneous Agents
  - 1. Various of the minor tranquilizers — Valium, Equanil, Librium, Vistaril, etc.
  - 2. Benactyzine (Suavitil), deanol (Deaner), benactyzine and meprobamate (Deprol)
  - 3. Various of the phenothiazines — Stelazine, Mellaril, Thorazine, etc.

In 1952 two hydrazine derivatives of isonicotinic acid, isonazid and iproniazid, were introduced in the treatment of tuberculosis. A number of individuals receiving these agents experienced elevation in mood.[5] Iproniazid, in particular, seemed to be a potent inhibitor of monoamine oxidase, an enzyme which facilitates the degradation of epinephrine, norepinephrine, and serotonin. Encouraged by the mood changes observed in tuberculous patients receiving iproniazid, investigators studied the effects of other monoamine-oxidase inhibitors in psychiatric patients. Initial reports were encouraging, with beneficial results reported in 50 to 80 per cent of depressed and schizophrenic patients,[6,7] many of whom had not responded to phenothiazines or electroshock. However, later studies have been generally less enthusiastic, although some have reported good responses in certain depressed patients.

Pharmacologic Action

In vivo examinations show that administration of monoamine-oxidase inhibitors of the hydrazine type results in the presence of increased amounts of the endogenous monoamines in various organs. This increase persists for several days and therapeutic doses have a cumulative effect. Besides elevating the monoamines in the brain, these agents increase the norepinephrine and epinephrine levels in the heart and the lactic and pyruvic-acid levels in the peripheral blood. An interesting clinical effect exploited in the treatment of hypertension is that these agents are also ganglion blockers, and large doses inhibit transmission through the sympathetic ganglia without equally depressing the function of parasympathetic ganglia. Hydrazine-type monoamine-oxidase inhibitors also influence a number of other enzyme systems; but species differences make elucidation of specific effects in man doubtful.[8] Table 2 illustrates the chemical formulae of the available compounds.

Not fully understood is the mechanism responsible for the principal *clinical effect* of the monoamine-oxidase inhibitors (psychostimulation, pain relief, alleviation of angina pectoris, and hypotension). Investigating the role of monoamine-oxidase inhibition is complicated by the variable potency of these agents from species to species. Consequently one can make only partial deductions about the quantitative action of monoamine-oxidase inhibition in man on the basis of animal experiments. Also, changes in the content of the amines and their metabolites in human urine do not necessarily reflect corresponding metabolic changes in the brain or myocardium. The organs contain a small fraction of the amines; the larger fraction is localized in peripheral depots (the adrenal medulla, etc.). However, the clinical effects of these drugs seem better correlated with monoamine-oxidase inhibition and changes of monoamine metabolism than with inhibition of any other enzyme system investigated to date. Of interest to nonpsychiatric clinicians is the apparent influence of monoamine-oxidase inhibitors on mesenchymal inflammation and connective-tissue growth.[9] Also, chronic-pain syndromes sometimes diminish or disappear, suggesting that these agents increase the threshold to certain types of pain.[11] Moreover, indolent ulcerations and certain burns have benefited from topical treatment with hydrazine monoamine-oxidase inhibitors.[10,12]

Early clinical effects include central nervous system stimulation, which may be manifested by mood elevation; in some instances

this may be paradoxically characterized by drowsiness or generalized relaxation. In certain patients no apparent effect on psychomotor state is observed. An effect on the autonomic nervous system occurs consistently, usually coincidentally with other physiological effects. Occasionally the effect of sympathetic or parasympathetic activity occurs before the mood change. This effect varies in severity and location in different individuals.

The Indications for Treatment

Illness generally treated with monoamine-oxidase inhibiting agents includes depression, especially prolonged depression with psychomotor retardation. The indirect stimulants are also useful in certain chronic neuroses and psychoses of other types. In addition, reports suggest these drugs to be beneficial in angina pectoris;[13] but whether they offer more than symptomatic pain relief due to analgesia and psychomotor stimulation is not clear. Like most subjective complaints, angina pectoris appears to be benefited considerably by the hydrazines in uncontrolled clinical trials, but when assessed with a placebo, benefit is difficult to prove.[14] When one considers the possible dangers of orthostatic hypotension or psychologically induced pain reduction, it seems sensible to use these agents conservatively in angina pectoris. The hydrazines and a nonhydrazine compound (pargyline) have also been used to treat hypertension.[15,16]

Since these agents cause widespread multiple effects in various systems of the body, *side effects* are somewhat difficult to define. The following are generally reported: vascular headaches, flushing, perspiration, lightheadedness, vertigo, postural hypotension, nausea, constipation, tremors, anorexia, increased appetite, urinary hesitancy, alteration in sexual activity, muscle fasciculations,* hyper-reflexia, clonus, edema, dry mouth, and paradoxical excitement. Serious toxic effects include necrosis of the liver, anemia, leukopenia, acute confusional and functional psychoses, and cardiac arrhythmias. Fever, hypertension and seizures sometimes occur when these agents are combined with imipramine, amitriptyline, desipramine, and nortriptyline.

There have been recent reports of catastrophic vascular reactions to the monoamine-oxidase inhibitors, and paroxysmal hypertension with severe headaches has resulted from their conjoint administration with sympathomimetic agents. Since 1963, a number of vascular crises have occurred after individuals taking these agents have ingested cheese, beer, broadbeans, etc., all of which contain large amounts of tyramine, whose potentiation may have been responsible.[17] In one large study of vascular disasters, approximately 8.4 per cent of patients receiving monoamine-oxidase inhibitors experienced acute hypertensive crises featuring intense occipital headaches and palpitation.[18] When patients are warned about ingesting cheese, processed milk products, and certain alcoholic beverages, the incidence of hypertensive crisis falls considerably. The biggest offender in this group of drugs has been tranylcypromine; but other monoamine-oxidase inhibitors are also likely offenders.

The hydrazine monoamine-oxidase inhibitors potentiate the pharmacological action of numerous unrelated drugs, including ganglion-blocking agents, barbiturates, anesthetics, corticosteroids, morphine, atropine, 4-amino-quinoline compounds, and alcohol. It is interesting to note that the diuretics, chlorothiazide and hydrochlorothiazide, potentiate the hypotensive effect of the hydrazines.

Assessment of Efficacy

At present, three indirect stimulants are available, namely, the hydrazines *isocarboxazid* (Marplan), *phenelzine* (Nardil), and *nialamide* (Niamid). The nonhydrazine *pargyline* (Eutonyl) was recently introduced as an antihypertensive agent. All have been assessed with and without placebo controls. Many uncontrolled investigations suggest that these agents are effective in many types of depression, especially in chronic, long-term depressions with somatic complaints and psychomotor retardation. The relatively rare, controlled investigations suggest the following: (1) Two large studies found isocarboxazid inferior to imipramine and placebo,[19,20] but three others found it more effective than placebo.[21-23] (2) Nialamide was also found ineffective in three controlled studies,[24-26] but according to another was superior to placebo.[27] (3) Four studies found phenelzine, like the others, inferior to electroshock.[20,28-30] Some controlled studies of phenelzine indicate it is superior to placebo,[31,32] but others indicate it is not.[20,28] (4) One controlled investigation found pargyline inferior to tranylcypromine.[33]

Tabulation of Specific Agents

Isocarboxazid (Marplan) — Its manufacturer and reports in the literature suggest that isocarboxazid is useful in various psychiatric disorders associated with depressive symptoms, withdrawal, or regression. It is provided in 10 mgm. tablets, and the usual starting dosage is 30 mgm. daily. Since its action is cumulative, dosage should be reduced to 10 or 20 mgm. a day after a week, or when the drug begins to have effect.

Nialamide (Niamid) — Indications are similar to those for isocarboxazid. It is provided in 25 mgm. tablets, and the suggested starting dosage is 75 to 100 mgm. daily in either divided or once-daily doses. Dosage should be increased gradually to 200 mgm. a day. After two or three weeks, or when a therapeutic effect is attained, one should gradually reduce the dosage to about 75 to 100 mgm. a day.

Phenelzine (Nardil) — Indications are similar to those for other members of the group. Phenelzine is provided in 15 mgm. tablets, and the suggested initial dosage is 45 to 75 mgm. daily, with a maintenance dosage of 15 to 30 mgm. a day being achieved after several weeks.

Pargyline (Eutonyl) — As a *nonhydrazine,* pargyline should not cause an appreciable incidence of liver dysfunction, although this is by no means certain. While suggested for use primarily as an antihypertensive, this agent does possess some antidepressant qualities; however, at present it is not suggested for use as an antidepressant.

Central Nervous System Bimodal Stimulants (Tranylcypromine)

General

Currently the only bimodal stimulant available is tranylcypromine (Parnate). This was the first of its group, and subsequent compounds have proved either ineffective or too hazardous for clinical use. Although in vivo it is one of the most potent monoamine-oxidase inhibitors, it differs from the hydrazine inhibitors in several ways, including the low incidence of liver and blood disorders associated with its use. Also, its cumulative effect is slight and dosage regulation is thus not so difficult. Finally, side effects like constipation, tremors, and sweating are less frequent. These benefits are, however, counterbalanced by the severe vascular catastrophes reported in 1963. For a time the drug was not marketed, and it has only recently been reintroduced. Table 3 gives the formula for tranylcypromine.

Pharmacology

An arylcycloalkylamine derivative somewhat similar in structure to the amphetamines, tranylcypromine is one of the most potent in vivo monoamine-oxidase inhibitors as measured by various pharmacological tests. Like the indirect hydrazine and nonhydrazine stimulants, it has monoamine-oxidase inhibiting properties; but it also has effects like those of the amphetamines, including a pharmacological antagonism to

TABLE 3
Bimodal Stimulants

Structure	Generic Name	Trade Name
	Tranylcypromine	Parnate

Continued

reserpine.[34] It will probably prove to have ganglion-blocking properties as well, since its side-effect pattern is in some ways similar to that of the other indirect inhibitors.

Indications and Assessment of Efficacy

Tranylcypromine has been used in the following clinical conditions: (1) neurotic depressions,[35,36] (2) retarded depressions[37] or (in conjunction with a phenothiazine) agitated, depressed syndromes,[38] (3) the withdrawn anergic, apathetic, chronic, hospitalized schizophrenic syndrome,[39] and (4) the multisymptom complex of somatic concern, anxiety, depression, and pseudoneurotic schizophrenia.[40] Controlled studies have indicated tranylcypromine is superior to placebo or reference compounds[41-43] but inferior to electroshock.[44] One recent investigation found that in combination with trifluoperazine it was superior to electroshock.[45]

Since the reports of vascular crises with tranylcypromine, the indications have been amended, and it is now indicated for severe depression in patients for whom electroshock is contraindicated or for whom no other drugs have been satisfactory. Also, tranylcypromine should be reserved for patients who are either hospitalized or under close supervision.

Side Effects

Side effects commonly associated with tranylcypromine are orthostatic hypotension, overstimulation, insomnia, weakness, headache, and palpitation. Rarer are drowsiness, dizziness, dry mouth, tremors, nausea, diarrhea, abdominal pain, bad taste in the mouth, and constipation. Anorexia, edema, blurred vision, chills, impotence, hepatitis and skin rash have been reported. Also rare are tinitis, muscle spasm, seizures, urinary retention, glaucoma, ventricular arrhythmias, and pulmonary edema.

Hypertensive crisis, the most serious reaction associated with the use of tranylcypromine, is characterized by some or all of the following symptoms: occipital headache which may radiate frontally, palpitations, stiff or sore neck, nausea or vomiting, sweating (sometimes with fever and sometimes with cold, clammy skin), photophobia, and dilated pupils. Either tachycardia or bradycardia may be present, possibly associated with constricting chest pains. Sometimes fatal intracranial bleeding has occurred.[46] In all patients taking the drug, blood pressure should be followed closely for evidence of any pressor response. One should not rely solely on blood pressure readings but also on frequent observations of the patient. Therapy should be discontinued immediately if palpitation or frequent headaches occur, as these may portend an incipient hypertensive crisis. If such a crisis occurs, the drug should be discontinued and therapy immediately introduced to lower blood pressure. Either pentolinium or phenotolamine is recommended.[47]

The contraindications specifically listed by the manufacturer are:[48] (1) Tranylcypromine is contraindicated in patients more than 60 years old, patients with confirmed or suspected cerebrovascular defects, and patients with cerebrovascular disease, hypertension, or history of headache. (2) It should not be given conjointly with imipramine, amitriptyline, desipramine, nortriptyline, pargyline, nialamide, phenelzine, or isocarboxazid; if any one of these drugs is given after tranylcypromine is discontinued, or if tranylcypromine is initiated after one of these drugs is terminated, the patient should be drug-free for one week. The drug should not be administered conjointly with any sympathomimetic agent, including the amphetamines and over-the-counter drugs such as cold, hayfever, or reducing preparations containing vasoconstrictors. (3) Patients should be instructed not to ingest cheese, broadbeans, processed milk products, beer, ales, and wine while taking the drug. (4) Also to be avoided are the antihistamines.

Tabulation of Specific Agents

The only agent in this group is tranylcypromine, which is provided in 10 mgm. tablets. Recommended initial dosage is 10 mgm. once or twice a day. After a week (provided no serious side effects occur), this dosage may be increased to a maximal daily dosage of 30 mgm. A suitable maintenance dose is 10 mgm. once or twice daily.

Central Nervous System Suppressants

Kuhn reported (1957) that an iminodibenzl derivative, imipramine, had antidepressant properties.[49] Since the monoamine-oxidase inhibitors were already clinically useful antidepressants, it seemed probable that this compound would have similar action. However, investigators found that imipramine and related compounds discovered at about the same time had many properties in common with the phenothiazines. Extensive clinical evaluations have demonstrated their value in many minor and severe depressive disorders, and they have, in general, proved beneficial in the agitated, depressive syndromes, especially in those of the involutional period. Side effects have consistently proven troublesome with adequate dosages. Table 4 illustrates the formulae for this group.

Pharmacology

All these agents exhibit weak to moderate activity similar to that of the phenothiazines. They impair the conditioned avoidance response, and other pharmacodynamic activities suggest similarity to the phenothiazines. Differences between the action of imipramine and the phenothiazines include the following: imipramine alerts the electroencephalogram; the phenothiazines sedate it. Imipramine and related agents potentiate the action of catecholamines, and all are antagonistic to reser-

TABLE 4
Central Nervous System Suppressants

Structure	Generic Name	Trade Name
	Imipramine	Tofranil
	Amitryptyline	Elavil
	Desipramine	Norpramin Pertofrane
	Nortriptyline	Aventyl

Continued

pine. In addition, amphetamine-induced psychomotor stimulation is slightly potentiated by subcutaneously administered imipramine, and imipramine and desipramine potentiate the effect of methyl phenidate, a central adrenergic agent, while chlorpromazine antagonizes it. In summation, the complex pharmacodynamic effect of these agents makes it difficult to assume a simple mechanism of action; the data imply, however, that they have anticholinergic, adrenosensitizing, and central nervous system stimulant properties.[4,50,51]

Indications

Although central nervous system suppressants are newer than the monoamine-oxidase inhibiting agents, they are in wider use, and it may be assumed that they are more acceptable to physicians. In uncontrolled studies, depressive states of diverse psychopathology have responded to imipramine, and claims of efficacy in the endogenous depressions have been particularly strong especially in manic-depressive reactions of the depressed type and involutional melancholia). The oldest of the three drugs are imipramine and amitriptyline, and both have delayed onsets of action; thus, an adequate trial requires two to three weeks.

Side Effects

Side effects of central nervous system suppressants include dry mouth, tachycardia, constipation, blurred vision, sweating, dizziness, weight gain, urinary frequency or retention, nausea, vomiting, orthostatic hypotension, and Parkinsonian tremors. Seizures, hypermanic episodes, myocardial infarction, fainting, skin rashes, and photosensitivity have also been reported. Hepatitis and bone-marrow depression, including agranulocytosis, are uncommon. Concomitant or temporally close administration of any monoamine-oxidase inhibitor should be avoided.

Assessment of Efficacy

Some controlled investigations on depressed patients have found imipramine significantly superior to placebo,[19,52,53] while others have not.[20,54] Controlled studies comparing imipramine to electroshock suggest equal efficacy at best[55] and inferiority at worst.[20] Imipramine has been found somewhat less effective than amitriptyline,[56] and both more effective[19,20,57] and less effective[21] than the monoamine-oxidase-inhibiting antidepressants phenelzine and isocarboxazid respectively. A study comparing it to tranylcypromine found the two comparable.[58]

Amitriptyline has also been found more effective than placebo.[59] Desipramine (Norpramin) has been reported to have a profile of activity similar to amitriptyline and imipramine;[60,61] controlled studies suggest it is superior to placebo[62] and comparable to imipramine.[63] Nortriptyline, another recently introduced central nervous system suppressant, is similar to other members of the group in indications,[64] and controlled studies suggest it is equal in efficacy.[65]

Individual Agents

Imipramine (Tofranil) — This drug may be given in a wide variety of depressive syndromes. It is supplied in 10 and 25 mgm. tablets and also in parenteral solution. Initial dosage should be from 25 to 75 mgm. a day, with a maximal daily dosage of 300 mgm. which should be given only under *very* close supervision. The average daily dosage is approximately 150 mgm. Dosage may be increased by 25 to 50 mgm. every few days, depending on toleration. The physician should exercise extreme care in administering imipramine to elderly patients because of the danger of orthostatic hypotension and cardiac arrhythmias. The claim that imipramine is effective in the treatment of enuresis[67] has been disputed.[68]

Amitriptyline (Elavil) — Greatly similar to imipramine, except that it is probably more sedative, amitriptyline is provided in 10 and 25 mgm. tablets. Suggested initial dosage is 75 mgm. daily, with a maximal daily dosage of 200 mgm. Dosage may be increased from 25 to 50 mgm. every three or four days. Contraindications and precautions are similar to those for imipramine.

Desipramine (Norpramin, Pertofrane) — This drug has an alleged rapid onset of action and was suggested for clinical use since it is a pharmacologically active metabolic product of imipramine. Twenty-five mgm. tablets are provided, and suggested initial dosage is 75 to 100 mgm. daily, followed by a week's rapid increment of up to 200 mgm. daily in divided doses. Side effects reported to date are similar to those for the group. Rarely, transient ataxia is seen, and a number of patients have reported a peculiar flushed, warm sensation of the skin.

Nortriptyline (Aventyl) — A recently introduced central nervous system suppressant with indications and possible adverse consequences similar to those for other members of the group, nortriptyline appears closer to amitriptyline than to imipramine on the basis of chemical structure. Capsules of 10 and 25 mgm. are provided. Recommended dosage is 20 mgm. daily initially, with subsequent increments to 100 mgm. daily. Hospitalized patients have received up to 300 mgm. a day; but more than 100 mgm. daily is not recommended.

Miscellaneous Agents Not Classified as Antidepressants

Minor or major tranquilizers are often helpful in depressive syndromes; used alone or conjointly with antidepressants, they benefit anxious or agitated patients who are also depressed. Achieving a satisfactory dosage is relatively easy and safe with the minor tranquilizers. Members of this group include meprobamate (Miltown, Equanil), chlordiazepoxide (Librium), diazepam (Valium), and hydroxyzine (Vistaril). Other minor tranquilizers are equally suitable. Common side effects are drowsiness, ataxia, skin eruptions, blurred vision, and with some agents, blood dyscrasias. Habituation and withdrawal symptoms (seizures) have been reported with a number of these agents.

Benactyzine (Suavitil) is difficult to classify; chemically similar to the minor tranquilizers, it appears to possess some mild antidepressant properties. When given alone, dosage is 1 to 3 mgm. daily; however, a combination of this agent and meprobamate (Deprol) appears to be of some benefit in mild depressive conditions. Alone or in combination with other agents, benactyzine appears to be only slightly beneficial[66,69] in classical depressive syndromes, but it may be fairly effective in common grief reactions.

Deanol — Another stimulant used in mild depressive conditions is deanol (Deaner). A tertiary amine differing only slightly from choline, this compound passes the blood-brain barrier and, theoretically, should be an active central nervous system agent. Unfortunately, it is only slightly antidepressive[69,70] and has been reported beneficial only in uncontrolled clinical trials. It does appear to be of some use in certain cases of mental defectiveness and in childhood behavior disorders. It is slow-acting, and the usual daily dosage is 50 mgm. Serious side effects are rare, but muscle tenseness, insomnia, pruritus, postural hypotension, constipation, and weight loss have been reported,

Antischizophrenic — The major tranquilizers are potent antipsychotic agents, and some are effective either alone or as adjuvants in the treatment of certain depressive syndromes. With a few exceptions, these agents have equal antipsychotic action;[71,86-90] differences are in degree of sedation offered, type and incidence of side effects, and possession of antidepressant properties. It appears that two members of the phenothiazine group are less effective than the others — promazine (Sparine) and mepazine (Pacatal). The three major groups of the phenothiazines are: (1) dimethylaminopropyl, (2) piperazine, and (3) methyl-piperidyl.[4]

The dimethylaminopropyl group offers the greatest sedation; this group is comprised of chlorpromazine (Thorazine) and triflupromazine (Vesprin). These drugs should be used cautiously in depressive disorders, as reports indicate they may occasionally intensify depressive symptoms.[72] However, one of them might prove useful in certain atypical schizophrenic psychoses (schizo-affective-type) or in profound psychomotor agitation.

The piperazine group is comprised of prochlorperazine (Compazine), trifluoperazine (Stelazine), perphenazine (Trilafon), fluphenazine (Prolixin, Permitil), thiopropazate (Dartal), acetophenazine (Tindal),

Continued

and carphenazine (Proketazine). These compounds have higher activity per milligram and fewer sedative properties than the dimethylaminopropyl compounds. Extrapyramidal symptoms are very common, but these agents are very useful adjuvants to the antidepressants. Also, some of them (trifluoperazine,[73] fluphenazine,[74] acetophenazine[75]) have been reported to have mild antidepressant properties. In any case, drugs of this class can be used alone or conjointly with antidepressants in agitated depressive syndromes.

The only member of the methyl-piperidyl group in wide use at present is thioridazine (Mellaril). This agent possesses a higher milligram potency than chlorpromazine and has no appreciable incidence of extrapyramidal symptoms. Thioridazine (Mellaril) has been studied most intensively and is useful alone or in combination in the depressive syndromes.[76,84,91]

Chlorprothixene (Taractan), another agent which resembles the phenothiazines, occupies an intermediate position between the major and minor tranquilizers and has been reported to have antidepressant properties.[77] Indications for its use as an antidepressant are disputed,[78] but it may benefit certain anxious and tense individuals. Side effects are similar to those of the phenothiazines.

The Rauwolfia Drugs (reserpine) are absolutely contraindicated in the depressive syndromes or in any medical illness complicated by depression.[79] These agents have some antipsychotic activity, but they also accentuate and perhaps cause certain severe depressive illnesses. In any case, these drugs are not as generally effective as the phenothiazines.[80]

Side Effects

Common side effects of the phenothiazines include blurred vision, dry mouth, constipation, weight gain, edema, vivid dreams, and, in high doses, seizures. Extrapyramidal symptoms, including pseudoparkinsonism, motor restlessness, opisthotonos,* and oculogyric* crisis are not uncommon, especially with agents in the piperazine subgroup. Jaundice, impotence, urinary retention, dermatologic disorders, and blood dyscrasias have been reported with various phenothiazines.[81] The usual problems in prescribing these agents are insufficient dosage and failure to recognize early extrapyramidal symptoms. Only clinical experience with several provides the acumen necessary for proper determination of adequate, safe dosage schedules.

Method of Application

The first consideration in using antidepressant drugs is to arrive at a satisfactory treatment diagnosis. Though psychiatric diagnoses are vague and consensus hard to achieve, rough categories of depressive syndromes do offer guidelines to drug choice. Of course, what follows is only one of many approaches, and there are always exceptions to the outline of syndromes and the suggested treatments. More importantly, the drugs are most effective when used with psychotherapy and are not substitutes for the hospitalization and electroshock that the desperately ill patient requires.

Grief Reaction and Depressive Syndrome

As a symptom, depression is a part of grief reactions and classic depressive syndromes and is accessory to other functional and organic syndromes. *Grief reactions* are common experiences that occur following loss, and the kinds of losses possible equal the variety of things we care for — health, loved ones, possessions, etc. Grief reactions may occur at all ages in all individuals and are associated with sadness, crying, remorse, and anger. In most people the loss and feelings associated with it are intimately connected, and individuals experiencing loss often avoid anything that reminds them of it. They describe waves of sadness and remorse on thinking about the trauma, but after a variable period, the process of mourning eventually ends. Strictly, a grief reaction is not a depressive syndrome, but it may precede a depressive illness.

True or classical repressive syndromes are differentiated from grief reactions and from each other by symptoms, premorbid personality characteristics, acuteness of onset, age, and clinical course. Psychiatrists describe these illnesses in a number of ways, but for purposes of drug therapy, a classification is here adapted from a number of sources.[82,83] It is stressed that the four syndromes are approximations for treatment purposes and not substitutes for official psychiatric nomenclature.

---

*See Test Your Word Score Page 1167.

Endogenous Syndrome

The first depressive pattern is termed the *endogenous syndrome* because symptoms occur in the absence of environmental disasters or, more commonly, are disproportionate to the precipitating crisis. Individuals with this syndrome have a dismal, hopeless outlook and severely impaired self-esteem. They relate profound guilt feelings and are usually withdrawn, isolated, and apathetic. Slow in speech and thinking, they complain bitterly about difficulty in concentrating. Though most psychological processes are retarded, their motor behavior may be agitated in spite of slowness in thinking, difficulty in concentrating and trouble in making decisions. They often have multiple physical concerns but are not in the truest sense hypochondriacal. Generally, the family describes the patient as "having given up" after a loss or internal conflict. The premorbid personality is often compulsive or cyclothymic.* If it is compulsive, the likelihood of agitation is greater; if cyclothymic, motor retardation is more likely. The symptoms have an insidious onset over a year or less, and frequently biological symptoms of depression (anorexia, weight loss, insomnia of the repeated-wakening type, and fatigue which is worse on arising) occur very early. This syndrome is rare before age 25; but from ages 25 to 40 it is commonly diagnosed as depressive reaction if it is not severe, and as either psychotic-depressive reaction or manic-depressive reaction (the latter if the premorbid personality was cyclothymic). After age 40, compulsive individuals are especially prone to experience their first serious depression and are frequently diagnosed as having an involutional psychotic reaction. Spontaneous remissions occur, but usually only after months or years.

Repressed Rage Syndrome

The second depressive pattern, frequently follows a sustained or major life upheaval. Repressed rage is mobilized and is frequently directed towards a loved one; sometimes this rage is not expressed, or, more commonly, it miscarries and appears as general irritability and annoyance over trifles. Such patients are also dismal and hopeless, with little self-esteem, but they are also anxious and may have other neurotic symptoms, such as phobias. Not uncommonly agitated, they make frequent clinging demands for attention. Biological symptoms of depression occur only after the syndrome is severe. Crying is frequent (in contrast to the *endogenous pattern*), and the physician has less trouble making a diagnosis. Premorbid personality usually is grossly normal, and the history suggests rather adequate adjustment before the upheaval which released the repressed aggression. Duration of symptoms prior to seeking help is usually a month or less. This pattern can occur throughout life but is frequent between the ages of 20 and 35. Commonly the pattern is diagnosed as depressive reaction or, if severe or if suicide is a feature, psychotic-depressive reaction. Occasionally, environmental situations will be such that symptoms persist for years (as in chronic-depressive reaction). Symptoms often remit spontaneously after three to six months.

Pseudoneurotic Schizophrenic Syndrome

Individuals suffering from the *latent or pseudoneurotic schizophrenic syndrome* have a long history of persistent multiple neurotic complaints (phobias, obsessions, conversions, dissociative states) and many bizarre, uncommon physical concerns. They are prone to bouts of anxiety, and their illnesses usually have variable amounts of depressive overtones. Attention to others and the world in general is reduced, and a mono-ideational concern with themselves and their bodily functions is often present. Duration of symptoms is hard to determine, since the usual

Continued

---

*See Test Your Word Score Page 1167.

history is a lifelong pattern of distress. Age of onset varies, but frequently the diagnosis can be made in the twenties, although for decades these individuals may appear neurotic or to have a bona-fide physical ilness.

Maladjusted Personality

Individuals who show the *maladjusted-personality-with-depression pattern* have a long history of personal maladjustment and are often at their best demanding, provocative, angry, and resentful. They are basically narcissistic and overaggressive individuals who dominate others by active or passive means. When thwarted, denied, or frustrated, or unable to continue their usual behavior, they become depressed, and not uncommonly their depression is used to influence the environment. Suicidal threats, thoughts, and attempts are common, and the patient is hard to treat, since impulsivity and destructiveness may be directed toward others. These individuals represent various personality disturbances including passive-aggressive, inadequate, psychopathic, and emotionally unstable personalities. Symptoms are acute in onset (usually a month or less) and often occur precipitously over several hours or days. Biological symptoms are rare unless the illness progresses for some time. The duration of symptoms depends on the environmental circumstances, but usually they last six weeks or less. They occur at all ages in such individuals, but are most frequent between the ages of 15 and 25.

The Choice of Drugs

Using the above classification, some rough rules may be applied to drug choice. *Grief reaction* is not a true depressive syndrome and seldom requires a potent antidepressant. One of the direct stimulants (amphetamines), deanol, or benactyzine can sometimes be helpful as an ancillary to compassion and support. Drug choice in the endogenous syndromes depends on psychomotor symptoms.

Quite *agitated and anxious patients* usually respond best to a central nervous system suppressant, and retarded, apathetic and generally slowed-down patients do best on an indirect or bimodal central nervous system stimulant. If other therapies fail, agitated patients can be tried on an indirect or bimodal stimulant in combination with a phenothiazine.

Depressions of *the suppressed-rage type* often fail to respond to antidepressants alone or are more benefited by a barbiturate or ataractic.* A good policy is usually to start therapy with a minor tranquilizer or a mild phenothiazine (chlorprothixene) for several days to one week. If the patient does not respond, one may then try either a central nervous system suppressant or an indirect stimulant in association with the tranquilizers.

Patients with latent or *pseudoneurotic schizophrenic syndromes* are best treated by a trial of a phenothiazine (trifluoperazine, fluphenazine, perphenazine, thioridazine, etc.) followed in several weeks by an adequate dosage of a bimodal or an indirect stimulant. This treatment should be continued for months to years.

Patients with a *maladjusted personality syndrome* should be handled with extreme caution; usually minor ataractics should be tried and the patient seen often (twice a week) before initiating an antidepressant. Because of their unreliabiilty, these patients probably should not receive monoamine-oxidase inhibitors of any kind but should be maintained on the central nervous system suppressants.

Depressions associated with other illnesses, both functional and organic, are best treated with central nervous system suppressants alone or in combination with ataractics. Occasionally an indirect or a bimodal stimulant may be helpful if there are no medical contraindications.

In combination therapy a good rule is to start one drug at a time. If a patient is anxious, fearful, or phobic, an adequate dosage of a minor tranquilizer is helpful. If he has agitation without psychological content (fear, phobias, etc.), a phenothiazine often helps. In a schizophrenic disorder, one should never give an antidepressant outside a hospital without the protection of a phenothiazine. It is best not to give more than one tranquilizer and one antidepressant, as multiple agents interact adversely, and if an untoward effect occurs, one cannot determine which drug is the offender.

---

*See Test Your Word Score Page 1167.

General Considerations of Treatment

Beyond the choice of drugs, one must consider the general pattern and means of treatment. Generally, one should see patients at least twice weekly at the beginning of therapy, both to supervise medications and to prevent suicide. Depressed patients are quite prone to disastrous despondency if therapy fails. In a patient in whom the role of depressive elements is in doubt, it is best to treat tense, restless and anxious symptoms with a minor ataractic and wait three or four days until the patient has a chance to collect himself. On occasion this is sufficient and the illness will abate spontaneously. If you are doubtful about the patient's reliability, avoid the monoamine-oxidase inhibiting drugs and use a central nervous system suppressant. In adequate dosages the central nervous system suppressants have a wide spectrum of activity and are the safest agents for older patients. After receiving adequate dosages for several weeks, there should be some relief of symptoms. If not, the patient should be reevaluated and hospitalization considered. If he is doing well, then weekly visits for three to four weeks (continuing the previous dosages) should be tried. By then the patient should be in reasonably good health, and maintenance therapy can be initiated. Maintenance therapy should continue for about three to six months, and the dosage gradually decreased during this time. After six months, one must try to discontinue at least the antidepressant (except in latent schizophrenic individuals). Occasionally chronic depressive reactions require longer therapy, but these are rare in general medical practice.

Abuses

The chief abuse in the use of antidepressant drugs is to prescribe large quantities for people who don't need them. A physician should not hesitate to discontinue all therapy in depressed patients after three to six months, unless he is reasonably sure the patient is chronically depressed. Another flagrant abuse is concomitant treatment with too many ancillary therapies. Not rarely patients receive one or more antidepressants, several tranquilizers, two or three analgesics, and several hypnotics at the same time. Since most patients with depressed syndromes have real potential for suicide and since the interaction of all these agents is fraught with many physiological difficulties, one should limit the therapy of a depressed patient to one antidepressant, one tranquilizing agent, and one hypnotic.

These agents are also abused in their use for the elderly. Senescence is a severe problem often accompanied by many untoward life experiences, and antidepressants are frequently ineffectual and actually dangerous because of their side effects. Chloral hydrate or a minor tranquilizer in conjunction with judicious counseling and placement will often accomplish more in the elderly than antidepressant medications. In regard to referral, it is best to refer any patient who has threatened suicide. Moreover, one should refer any patient who does not get better within three to six weeks. Depressive syndromes generally begin relenting fairly early in the course of therapy, the only exception to this being that some central nervous system suppressants and indirect stimulants take several weeks to work.

Summary

Antidepressant drugs are indicated for central nervous system stimulants or central nervous system suppressants, but general precautions should be observed in prescribing these drugs in specific disorders.

Abstracts, Briefs and Commentaries

MANAGEMENT OF MALIGNANT PLEURAL EFFUSION

Kinsey et al. obtained good results in the treatment of malignant pleural effusion by the instillation of 30 mg. of mustrogen hydrochloride diluted in 150 cc. of isotonic saline. They instilled this into the pleural cavity with a tube, left it for several hours and then removed it. Eighty-seven per cent of their cases were adequately controlled, and in the group of 62 patients the survival time was extended 11.6 months in those patients whose malignant pleural effusion was due to carcinoma of the breast.

The procedure is simple, requiring no special equipment, merely a small trochar and the insertion of a catheter in the pleural space where it is left until the treatment is finished. The effusion is first removed, the mustrogen is then instilled, and that too is removed after several hours. This may offer a possibility for a patient requiring repeated pleuracentesis in order to obtain comfort in breathing.

PRIMARY LYMPHOMA OF THE THYROID GLAND

The literature on primary lymphoma of the thyroid gland is reviewed, and nine additional cases are presented. In view of the longevity statistics (patients with primary lymphoma of the thyroid gland living from four years up to 18 years in one case), one should consider the prognosis to be more favorable than heretofore quoted. The current therapy for primary lymphoma of the thyroid gland depends upon whether the disease is localized, invasive, or disseminated. Several authors have stated that a probable relationship exists between lymphoma and lymphomatous thyroiditis (Hashimoto's disease), but statistically it cannot be held significant considering the number of cases of Hashimoto's lymphomatous thyroiditis treated throughout the world.

APPENDICITIS IN PREGNANCY

In 74,000 obstetrical patients admitted to Los Angeles County Hospital between 1957 and 1961 the incidence of acute appendicitis in pregnancy was 0.05 percent. A study of 36 cases clinically diagnosed as appendicitis in pregnancy showed that the fetal and maternal morbidity and mortality were reduced when a definite operation was done early.

The difficulty of diagnosis is increased in these cases by the need to consider pyelonephritis and twisted ovarian cyst.

Rupture of the appendix reduced the chances of maternal and fetal survival. Threatened premature labor may indicate a ruptured appendix. In such cases an emergency operation with the use of antibiotics was effective.

The incidence of premature delivery was proportionate to the delay in operating. If operation was performed within eight hours of admission there was no maternal or fetal loss. A delay greater than eight hours resulted in a 17 percent fetal loss in premature deliveries and a 4 percent loss of infants at term.

REVERSAL OF RENAL HYPERTENSION

Griffiths and Schwartz have indicated that there are four major baroreceptor areas, two in the carotid sinuses and two situated in the aortic arch. The central nervous system serves as the afferent limb of the baroreceptor reflex and transmits to the vasomotor center the action potentials from the carotid sinuses, as these areas have been considered to be stretch receptors and are presumably activated by the intraluminal pressure of the carotid artery, which, when stimulated reflexly, lowers the blood pressure, induces bradycardia, increases cardiac output, and diminishes venous return. The converse situation is noted when the pressure within the receptors is lowered.

These authors, using an electrical stimulus to the carotid sinus area of the dog, were able to observe a reduction in the hypertension which had been experimentally induced.

The clinical application of this electrical stimulation of the central nervous system, as a method of reducing blood pressure in hypertensive patients, is being done, and merits further study.

POSTMYOCARDIAL INFARCTION SYNDROME

The features of the postmyocardial infarction syndrome are presented, and the radiographic findings in 11 cases are reported, with 2 cases being described in detail. It is important that the syndrome be promptly recognized, not only so that proper therapy can be instituted, but to prevent improper therapy that may prove fatal. Radiologists should be aware of this newly recognized complication of a myocardial infarction since the condition may be first suspected from radiographic findings, and because it offers another explanation for the nonspecific findings of cardiac enlargement, pneumonitis, and pleural effusion. The syndrome is easily confused with an extension of the original myocardial infarction, heart failure, and pulmonary infarction. The etiology is not known. Treatment is discussed.

L. E. CELLS IN LYMPHOMA

Positive lupus erythematosus (LE) cell tests were obtained in two elderly women with lymphoma: the necropsy diagnoses were lymphosarcoma and Hodgkin's disease respectively. In the patient with lymphosarcoma, the LE cell test was positive on 24 occasions, and positive results were obtained in tests for thyroglobulin antibody and rheumatoid factor: treatment with radioactive phosphorus was beneficial. The Coombs test was positive in both patients. The origin of antinuclear and other autoantibodies in these cases was attributed to the development of self-reactive "forbidden" clones of lymphoid cells as a consequence of neoplastic change in lymphoid tissue. Lymphomatous conditions with autoimmune features could represent release of a range of abnormal clones of lymphoid cells, in line with Burch's concept that leukemia is dependent on a combination of germinal and somatic mutation.

READABLE WRITING

Busy physicians do not have time to wade through tediously written material. Too many complex words and too many long, involved sentences produce reports that might be best described as scientific gobbledegook. Writing ought to be simple and clear. The reader will read more, in less time, and understand better. Medical writing does not have to be stuffy or dull. It would be more interesting and useful if authors would use plainer words, shorter sentences, more compact paragraphs, and more direct style.

SMALL-BOWEL NEOPLASMS: ELUSIVE SOURCE OF ABDOMINAL SYMPTOMS

The surgical records and autopsy findings of 78 patients with primary small-bowel neoplasm are analyzed in an attempt to define the diagnostic problems presented by such neoplasms and to suggest methods of treatment. Malignant lesions were present in 74.4% of 43 symptomatic cases. The symptoms included nausea and vomiting, abdominal pain, abdominal tenderness, intestinal obstruction, palpable mass, intestinal hemorrhage. The diagnosis was established preoperatively in 53% of symptomatic cases by X-ray examination. Most of the failures in diagnosis occurred because a possibility of small bowel tumor was never considered in the differential diagnosis. In a few cases, laparotomy is the only diagnostic recourse; it is justified when the patient's case has been properly evaluated and roentgenograms have been revealing, but suspicion exists.

PITFALLS IN THE DIAGNOSIS OF PANCOAST TUMOR

The Pancoast syndrome is a well defined one that may have a longer clinical history than was previously believed. Four of the author's 11 patients had a history of over six months, and two had a history of at least two years. With recent improvement in therapy, significant cure and palliation can be accomplished, and an earlier diagnosis may better the results. With routine chest films, seven of the 11 cases were not diagnosed. With the addition of an anteroposterior spine film and apical lordotic and oblique films of the apices, however, all were readily recognized. Six patients had bone destruction, and five a soft-tissue mass only. It was surprising how much bone destruction could be missed on a routine chest film. Fluoroscopy with barium contrast along with laminagrams, added to the diagnostic study. If there is a suspicion of a superior sulcus tumor, routine chest films, and anteroposterior dorsal spine roentgenograms, and lordotic views should be the minimal examinations, and with these very few lesions will be missed. If these measures are not diagnostic, additional special studies should be performed.

CRITIQUE OF THE VIEWS OF DR. THOMAS SZASZ ON LEGAL PSYCHIATRY

Dr. Szasz, a professor of psychiatry at the State University of New York (Syracuse Branch) has become a reckless public critic of organized psychiatry and indirectly of organized medicine. He maintains that there is no such thing as mental disease and is a proponent of individual freedom that goes beyond the limits of reason and practicality. In fact, he would do away with all enforced psychiatric hospitalization and would allow individuals full liberty to injure themselves, even to the point of suicide. While it is true that abuses can and do occasionally occur in commitment procedures and during psychiatric hospitalization, they will not be prevented by the intemperate writing of Dr. Szasz, which is marked by gross distortions and inaccuracies. Although some of the views expressed in his latest book are provocative, it performs a great disservice by needlessly alarming the families of hospitalized patients and by providing the ill-informed critics of psychiatry with inaccurate data and specious theories.

HODGKIN'S IN PREGNANCY

A review of 35 cases of pregnancy associated with Hodgkin's disease revealed that in 28 women the disease was discovered during pregnancy, in 18 during the first trimester. Of the total number, 28 were delivered normally at term. Four of the pregnancies were terminated early by spontaneous abortion, all in patients who had become pregnant after the onset of the disease. No stillbirths or congenital anomalies occurred. A surprisingly large number of patients failed to become pregnant a second time. Pregnancy did not affect survival time; however, it was shorter in patients over 35 years of age as compared with the survival time of those under 35, regardless of whether they previously had children or not. No evidence was found that gestation accelerated the course of the disease. Interruption of pregnancy is not indicated on the basis of evidence presented in this series.

Book Reviews

Laws die, books never. — Bulwer-Lytton

STEREOSCOPIC MANUAL OF THE OCULAR FUNDUS IN LOCAL AND SYSTEMIC DISEASE — F. C. Blodi, M.D. and L. Allen, M.D., St. Louis, C. V. Mosby Co., 1964. Illustrated, including 105 stereoscopic color photos and viewer, index. Price $32.50.

The authors have developed a simple method of taking stereophotographs of the ocular fundus by slightly rotating the Zeiss fundus camera for the second exposure. This volume supplies the fruits of their labor for armchair viewing with the collapsible instrument included. There are 15 viewing reels, divided into various disease categories such as hypertension, tumors, diabetes, etc., covering the high points of most eyeground changes seen, not only by the ophthalmologist but by the internist, neurosurgeon, or anyone who has occasion to use the ophthalmoscope. Accompanying each view is a description of the patient and the disease, many of the descriptions accompanied by black and white photomicrographs of the histopathology, enabling one to get a good idea of the correlation of gross and microscopic pathology.

This is a truly beautiful medical book and is a delight to own and browse through.

W. S. McClanahan, M.D.

MARRIAGE COUNSELING IN MEDICAL PRACTICE — edited by Ethel M. Nash, M.A.; Lucie Vessner, M.D. and D. Wilfred Abse, M.D. and published by the Van Rees Press, New York, 1964.

The title of this book, "Marriage Counseling in Medical Practice," tells exactly what this book is about. It is a symposium written by a group of authors who in general do an excellent job from the viewpoint of the practicing physician with a difficult subject.

This book is of value to any physician regardless of specialty or interest, and particularly to medical educators in order to aid them in focusing their attention on the preparation of medical students and doctors in the area of marriage conflict. Marital problems are frequently the basis for many symptoms which bring patients to physicians. The book will help the physician handle more effectively some of the problems that result from marriage conflict, but more important, it may make him anxious enough to agitate for more facilities to better train him in the field of marriage counselling.

Even for the psychiatrist, who is probably the best trained of all physicians in the area of marriage counselling, this book has much to offer, although some may disagree with some of the ideas presented in the book.

Irving C. Bernstein, M.D.
Minneapolis, Minnesota

"SIGNS AND SYMPTOMS" — Cyril Mitchell MacBryde, J. B. Lippincott Co., 1964. 971 pages.

This is the Fourth Edition of MacBryde's "Signs and Symptoms."

The word symptom is used to name a manifestation of disease, which is usually a subjective observation from the patient.

Pain being a significant sign, the book contains eight chapters dealing with pain, originating from the various sections of the body. By using the table of contents, the reader is able to guide himself into the proper chapter, which may be of interest to him at the moment.

Generalized vasospasm, tachycardia, cough, hemoptysis, dyspnea and cyanosis direct the reader to a series of chapters devoted principally to cardiovascular and respiratory disease, and then there are a series of signs which direct one to the diseases of the gastrointestinal and biliary system.

Bibliographical references are tendered at the end of each chapter and these, though not extensive, seem to be adequate for more specific reference to the contents within each chapter.

I have found this to be an excellent edition, as a reference for a large variety of signs and symptoms that one encounters from day to day.

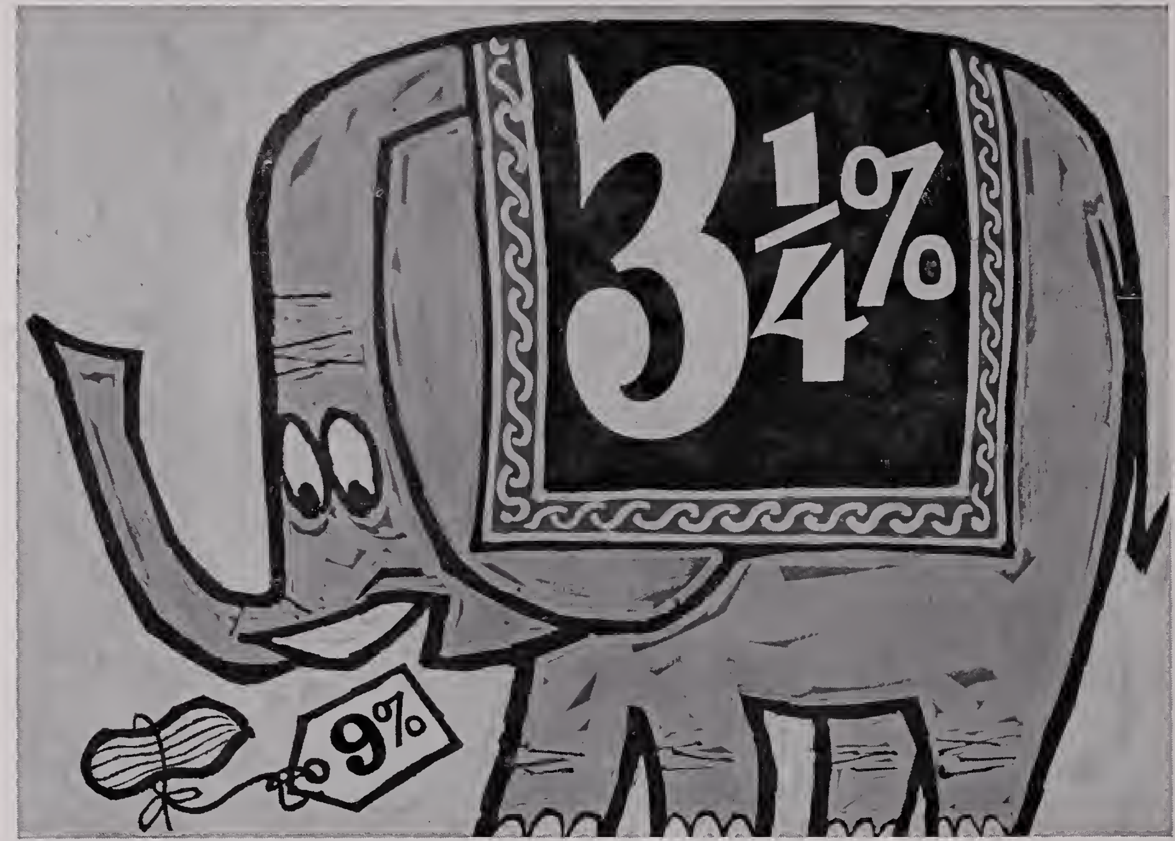
Riddle:
When is 3¼% larger than 9%?



Answer! When it represents *keepable* income from tax-free municipal bonds! A 9% yield from ordinary stocks may seem like a nice profit. But, it's really small peanuts, if you're in a high income bracket. Reason? Federal and state income taxes can take a huge amount of that profit away. Not so with *tax-free* municipal bonds! They allow you more "keepable" income . . . more big peanuts to salt away in your trunk! First National Bank offers a large selection of these bonds. Sound good? Then mail the coupon below for our free booklet "The Story Behind Municipal Bonds," as well as our handy "Tax Exempt Versus Taxable Income Table." Both give you vital information that can save you money. Or call our Investment Department (221-9463). So make like an elephant—don't forget—tax-free bonds can give you more *keepable* income!

Vignettes of the Surgical Horizon and the Surgeon's Image

New and Old*

OWEN H. WANGENSTEEN, M.D.**
Minneapolis, Minnesota

Anyone and everyone who offers a paper for presentation is offering himself as well as his ideas for inspection by his Fellows. I am always intrigued and stimulated by the young man who makes an all-out effort and comes up with a mature presentation of his assigned subject. When he passes the inspection with credit, he receives at the hands of his associates enhanced opportunities for growth and development.

Such inspection is a recurrent and lifelong process. At my time of life, after many years amongst you, perhaps the only useful purpose served by my appearance tonight is to provide you with an opportunity of advising whether I am ready for superannuation. Oliver Wendell Holmes once said, "Old age calls on us at age 50 and leaves his calling card." I have accumulated almost a "full house" of such cards, but the satisfactions of study and application are so pleasant and rewarding, I have resisted any summons to retire from the professional scene, even though the beckoning voice of the vesper bell of retirement occasionally titillates my eardrums agreeably.

However, my being with you tonight offers me the unique opportunity of indicating to the surgical profession of this community my deep appreciation of years of devoted and selfless service by many of its members to the Medical School and its Department of Surgery. And to all of you, I want to say on behalf of the School and particularly the Department, how very grateful we are that over long years the school has had and continues to have the confidence and the support of the profession. It has been pleasant to work in an environment in which the stimulus and the support of friends continually urge one to do his best. It was, therefore, with a sense of high privilege that I accepted your gracious invitation to be with you tonight.

---

*Presented at the Annual Meeting of the Minneapolis Surgical Society, April 7, 1965.

**University of Minnesota Medical School, Department of Surgery, Minneapolis, Minnesota 55455.

Continued

My entire professional life has been spent within the walls of a university. This discussion, therefore, will reflect the bias and the limitations of one who has not been exposed to the give-and-take of medical practice as most of you have. Even so, our problems in many particulars are probably very much alike.

My primary role has been that of conducting the affairs of a rather large clinical department, to teach undergraduate medical students, to supervise the instruction of graduate students in surgery and to integrate the professional services of a complex staff working in several satellite institutions. It has been a unique and wonderful opportunity, which, after all, is a professor's best paymaster.

My role has essentially been that of sideline cheerleader and regimental water carrier, but my most important function, I have come to believe, has been in trying to create an atmosphere sympathetic and friendly to learning—an environment in which scholarship and industry thrive, bringing out the best latent qualities of men. Men and the proliferation of ideas, emerging and generated in such a milieu, almost invariably prove to be every teacher's greatest discovery.

Changes on the Professional Scene

Senior, as well as latter-day general surgeons, are well aware that the surgical arena is changing. The surgeon of my training days was schooled to believe he could learn to do most operations reasonably well. With the advent of the many specialties of neurosurgery, orthopedics, urology, proctology, plastic, thoracic, and intracardiac surgery, he has come to realize that colleagues in all these related responsibilities achieve a level of competence to which the general surgeon cannot pretend. All surgical specialties now appreciate the importance of research in the training of surgeons. Over a number of years, I have been convinced that our best surgeons are products of the experimental laboratory. The time will certainly come when the young surgeon will acquire his primary surgical skill in the laboratory rather than on the wards, as is still current practice. When a young surgeon has demonstrated his skill in operating on the dog, he is ready for operations on man. A distinguished British surgeon remarked some time ago, while visiting our laboratories, what a great advantage the young American had in the opportunity to become a reasonably accomplished surgeon before making his first incision into human flesh.

Today surgeons do not suffer any embarrassment over taking a long time to do an operation well. Up until the beginnings of World War II, the time factor was a matter of the greatest concern in the performance of all operations. I was privileged a few years ago to watch a well-known Norwegian surgeon operate for coarctation of the aorta. After applying the hemostatic clamps, he took a twenty-minute period for refreshment before addressing himself with superb skill and energy to making a nice arterial anastomosis. Forty years ago, such behavior certainly would have resounded throughout the hospital and become a matter of common public knowledge in the surgical community before the day was out.

Many changes have occurred on surgical wards over the past five decades since World War I. As recently as three decades ago, patients with empyema, osteomyelitis, and goitre were frequent occupants of surgical wards. The effectiveness of antibiotics virtually eliminated the first two. Implementation of Marine's thesis that goitre is essentially an iodine-deficiency disease has made cancer, rather than exophthalmic goitre, the most common surgical thyroid disease. Tuberculosis of bones and joints and tuberculous lymph nodes have disappeared from the scene, largely as a consequence of pasteurization of milk and the slaughter of diseased cattle. Pulmonary tuberculosis too, which usurped the attention of the thoracic surgeon three decades ago, has almost vanished from hospital wards as a consequence of isolation, streptomycin, and pharmacologic adjuvants.

Patients with acute appendicitis today, well cared for in their own communities, are now a rarity upon the wards of a University Hospital. The 95-percent decrease in the mortality of appendicitis[1] that has occurred at the national level over the past 35 years is due to earlier surgery and improvements in surgical care and appreciation of the potential hazard of luminal obstruction of the appendix which is capable of a secretory pressure approximating systolic blood pressure. The mortality of peptic ulcer perforation has been greatly lessened by timely surgery and antibiotic therapy. The persistent mortality of peptic ulcer today is essentially that of massive hemorrhage, upon which use of gastric cooling has begun to make an impress. Definitive control of the peptic ulcer diathesis awaits elucidation of a number of factors in its potentiation and the development of more effective nonoperative methods to combat acid peptic activity. Gastric freezing is often attended by dramatic early but somewhat disappointing late results. Its efficacy as an anti-ulcer agent is still on trial.

A 50-per cent reduction in mortality from bowel obstruction has occurred over the past 30 years. McKittrick and Sarris[2] (1940) reminded the profession 25 years ago that no significant improvement in the mortality of intestinal obstruction had been observed at the Massachusetts hospitals in the 50-year period beyond 1890, until introduction of better techniques of nonoperative and operative decompression and earlier surgery became the order of the day. Today in some hospitals, including our own, the hospital mortality for acute simple obstruction with viable bowel is approximately 1 per cent for the small intestine[3] and 5 per cent for the colon. Delay, strangulation, perforation and the difficult obstructions of the newborn account largely for the persistent morality. General implementation of well established techniques should presently be reflected in additional important gains detectible in our vital statistics.

Surgery of the Heart and Large Arteries

The most exciting development in surgery in the past dozen years has been in treatment of heart disease, once solely the domain of the internist. Courageous and aggressive surgeons are now repairing congenital defects of the heart in large numbers with mortalities no greater than those attending operations dealing with more prosaic lesions.

Intracardiac surgery is essentially a development of physiology and reflects the importance of training in adapting techniques from other disciplines. Simultaneous progress in angiography and telemetry came also as great and fortunate boons to the cardiac surgeon.

Heart valve replacement is an even greater challenge involving engineering skills. Imaginative surgeons are toying with mechanical pumps and small reservoir devices to replace the heart, while others have built hyperbaric oxygen chambers which may come to supplant extracorporeal circulation for a few conditions during cardiac bypass.

Pacemakers are permitting a normal life to a large number of patients. Control of blood pressure by similar means is currently under surveillance. Perhaps presently, one may see such devices available to energize respiration, to control motion in paralyzed extremities, or perhaps even to take over the complicated functions of the liver and of the kidney. If and when we learn how to prevent rheumatic heart disease and congenital cardiac deformities, cardiac surgeons will channel more thought and effort to the challenging problem of dealing with obstructions in the coronary and peripheral small arteries of the brain and lower extremities.

The cause of atrophy of the islets of Langerhans in diabetes is still a puzzling enigma. Surgical efforts directed at improving the arterial circulation of the pancreas in diabetes could prove rewarding.

Corrective surgery for replacement of large arteries has been a great achievement in the last decade, yet the basic information relating thereto had been available for nearly fifty years. Alexis Carrel was given the Nobel Prize for his important contributions to blood vessel anastomoses in 1912, an award which some modern students feel should properly have been shared by his associate, Charles Guthrie. The coming of heparin obviously played a significant role in the harvest and extension of life which has rewarded the surgeon's aggression upon degenerative diseases of major arteries.

Continued

Slow Evolution of Antiseptic Surgery

The importance of looking backward in experience as well as forward in experiment must not be forgotten. Thus, as one looks back, it is quite obvious that antiseptic surgery might well have come two decades earlier, had the mood of acceptance been warmer in 1847 when Semmelweis introduced chlorine compounds for hand disinfection. A Jacob Henle[4] (1840) and a Louis Pasteur[5] (1861) were necessary to point the way to the role of bacteria in the genesis of wound suppuration. It was the brilliant observations of Julius Cohnheim[6] (1861-73) upon leucocytic diapedesis* and filtration of fluid and cellular elements from the blood vessels at the site of injury which laid the foundations for the modern views of inflammation. Cohnheim's observations made John Hunter's[7] phlebitic theory of inflammation obsolete and similarly outmoded Virchow's[8] thesis of total participation of all tissues at the site of injury in the inflammatory process. Lister's[9] observations on compound fractures and the important work of Robert Koch[10] in separating out pure cultures of bacteria helped to make the work of Pasteur more intelligible and to break down the stubborn resistance to acceptance of antisepsis. Koch's work also hastened assimilation of asepsis into hospital practice. Reintroduction of the antiseptic spray of Lister in a new form is very much needed today, as well as new techniques of operating room ventilation to reduce the hazard of air contamination during operations.

Insulin, vitamin B_{12}, cortisone, and antibiotics are miracles of our age. It is to be hoped these significant discoveries will be matched by development of pharmacologic or immunologic inhibitors which will suppress anomalous organ function and control peptic ulcer, hyperfunction of the hypophysis, parathyroids, adrenals, and aberrant tissue growth and lend encouragement as well as accomplishment to the heroic efforts of surgeons in their attack upon the problem of homografting of organs. The stumbling block of a skein of immunologic enigmas will have to be disentangled before homografting is ready for general clinical application.

Cancer

In an address in 1897, W. W. Keen,[11] a well-known American surgeon, regretted he would not be alive in 1947, for the passage of 50 years he believed would certainly see the conquest of cancer. The late King George V proved a far better prophet. In addressing the First International Cancer Conference in 1928, the King said through his counsellors: "I note with interest that your object is research, both into the cure and causes of cancer. No doubt in the last resort the discovery of the cause is the only certain and absolute means of cure. But I am glad that you have not ignored the practical side of the problem. Remembering the thousands of sufferers from cancer, I feel that if your discussions lead to advance in diagnosis, treatment, or even palliation of the disease, this conference will have justified itself and earned the gratitude of mankind."[12] — suitable words of introduction for many a cancer conference held during intervening years.

A nearly 50-per-cent decrease in the mortality of cancer of the cervix at the national level has occurred over the last twenty-five years owing solely to a responsive public learning to appreciate the worth of the Papanicolaou Test in detecting early cervical cancer. Similarly there has been a 12-per cent reduction in the mortality of cancer of the rectum owing to acceptance in many areas of the value of an annual proctoscopic examination in the detection of early cancer of the rectum.[13] Studies of our Cancer Detection Center, an activity which has been fortunate to have had a favorable nod from the Cancer Committee of the Minnesota State Medical Society over the past 17 years, suggest that cancer of the rectum may also come to be a disappearing disease. Cancer of the large bowel, involving both rectum and colon, is the largest contributor to deaths from any organ inasmuch as it is a frequent cancer in both sexes. A similar reduction in cancer of the colon beyond reach of the proctosigmoidoscope must await development of more precise roentgenologic techniques of cancer detection. Perhaps the most surprising and rewarding finding of our Cancer Detection Center Studies is that an annual examination of the breast, in the hands of interested and experienced personnel, suffices to detect breast cancer sufficiently early so that the five-year survival amongst women in that group has been 90-per cent — a 100-per cent improvement over the current situation relating to patients arriving at the outpatient clinic of our hospital with a clinical diagnosis of breast cancer.[14] Until major breakthroughs occur that will drastically change cancer management, cancer detection clinics must be looked to as a practical and very worthwhile direct attack upon the problem of cancer.

---

*See Test Your Word Score Page 1167.

I have heard Dr. Donald J. Cowling, great Minnesota citizen, when listening to narration of circumstances carrying overtones of self-service, utter the telling remark: "Noble Soul!" Any such suggestion detectible in the foregoing account will serve only to indicate that some of these gains are due to the work of my colleagues.

Inventory of Surgeons' Wishes

Among innovations, longed and hoped for, the following are undoubtedly near the top of most surgeons' wishing inventory:

1. Pharmacologic or antibacterial agents to eliminate or control pyogenic infection.
2. Simpler and more effective hemostatic agents, as well as anticoagulants.
3. Simpler and even more effective anesthetic agents.
4. Effective means of sustaining a normal circulation in shock.
5. Means of accelerating wound repair.
6. Mechanical devices to simplify operative procedures upon small tubular structures.
7. Techniques to ablate the antigenic properties of immune reactions which continue to retard development of organs.

It is undoubtedly to the interdisciplinary facets of biochemistry, biophysics, bioradiology, microbiology, experimental pathology, pharmacology, and physiology, that we must look for new tools and techniques which can make these needs a reality.

Challenging Problems

We have had the unique opportunity of witnessing a most dramatic and telling consequence of the results of research over the past decade upon a world-wide scourge. In 1953, the Metropolitan Life Insurance Company paid death benefits to the families of victims of poliomyelitis in the amount of $658,000; a decade later the outlay was $7,000.[15] How wonderful to observe the disappearance of this menacing crippler! Strange as it may seem to us in Minnesota, malaria causes more disability and takes more lives than any other disease. Tuberculosis too continues prevalent in many areas of the world, pointing up very obvious geographic differences in health problems. At the turn of the century, pneumonia and tuberculosis were reported as the first and second causes of death in the United States. Twenty years from now most infectious diseases will probably be well controlled, almost universally.

Today, heart disease in its many manifestations, cancer, trauma, and congenital deformities account for more than 75 per cent of deaths in our country, revealing what public health measures and the combined wisdom of all the health sciences have yet failed to influence significantly. At best, death can only be postponed. President Johnson's proposal of an all-out frontal attack upon heart disease, stroke, and cancer reflects the suggestion that redeployment of medical investigative talent in heavier concentration upon these diseases will cause these formidable and menacing foes to retreat and capitulate. There is yet no detectible "soft under-belly," to employ a Churchillian characterization, apparent in the armor-plate of any of these disorders. Campaigns, military and other, have to be fought with available tools and ammunition. While we await the development of scientific tools which can carry the battle to the innermost sancta of the redoubts of these well entrenched enemies there must be no let-up in the scientific attack upon a host of other diseases with more overt evidences of cracks in their topography.

Medicine — An International Language

There are no areas of confidential information in medicine. An important discovery made on one continent is editorialized by medical journals everywhere and quickly becomes the property of all the peoples of the

Continued

world. The late President, John F. Kennedy, spoke of this international aspect of science in addressing the Centenary of the National Academy of Science just a month before his tragic death. "The great scientific challenges," he said, "transcend national frontiers and national prejudices. . . . The language of science has always been universal . . . but the contemporary revolution in transport and communications has dramatically contributed to the internationalization of science . . . and the increase in organized international cooperation." Medicine, more than any other activity or discipline, makes the whole world kin. When the quality of sympathy and community of feeling, at the basis of all good medicine, enter more freely into all human enterprises, the problems of food and shelter for all and of education for our children will loom less formidable and unremediable than they now appear in many parts of the world. Society and medicine together are working unrelentingly to set aside the dictum of natural selection by the survival of the fittest. Society is no longer content to leave the straggler and the handicapped to their own fate. With medicine as a strong ally, a large proportion of such persons today can be salvaged for lives of usefulness and personal fulfillment.

War, Pestilence, and Disease

Throughout the ages, war and pestilence have been the chief levelers of population growth. Medicine and society have succeeded in eliminating many of the plagues which, through the centuries, have decimated peoples in all areas of the world. Yet struggles for advantage continue unabated.

The final lessons of most wars have been their utter futility. There were eight million battle casualties amongst all combatants in World War I; 10 million in World War II; in addition, approximately 15,000,000 civilians were killed by massacre, starvation, ill treatment, disease, and bombing.[16] More than two thirds of the nine million Jews in Europe were annihilated, an outrage to the dignity and humanity of man which must plague the conscience of all for centuries to come.

The horror and holocaust of war should persuade the peoples everywhere to learn to resolve their differences, with advantages for all. Many here this evening know of the deprivation suffered during the German occupation by surgical friends in Holland, Denmark, and Norway. At war's end, some of them affected not to understand when addressed in German. Mrs. Wangensteen and I were privileged to attend the German Surgical Congress in Munich a year ago. Its President, Rudolf Nissen, distinguished Professor of Surgery at Basel, had been exiled by Hitler from his position in Berlin at the beginning of hostilities in World War II. At an informal gathering for foreign guests of the Congress, the well-known Danish surgeon, Erik Husfeldt, leader of the Underground Resistance Movement in Denmark during the war, speaking in German, proposed the toast to German surgeons and surgery. Such an occasion indicates that man is willing and able to overlook and forget his worst hurts, once etched deeply on his memory. The passion of resentment, if constantly rekindled, only consumes. If all man's efforts were directed at improving our common lot, what a different place this world could be!

Surgery's Dependence Upon Other Disciplines

In writing of his earlier training days in Berlin (1835-40), Jacob Henle (1882) said important discoveries could be "achieved by scratching a membrane with the nail or a scalpel." The British anatomist, Sir Robert Christison, likened Anatomy to a harvest field. "First come the reapers," said Christison, "who enter upon untrodden ground and cut down great stores of corn from all sides," amongst which group he listed Vesalius, Fallopius, Malpighi, and Harvey. "Then come the gleaners, who gather up ears enough from the bare ridges to make a few loaves of bread," in which group he mentioned Valsalva, Haller, Winslow, Hunter, and others. "Last of all," said Christison, "come the geese, who still contrive to pick up a few grains scattered here and there among the stubble, and waddle home in the evening, poor things, cackling with joy because of their success."[17] "We are the geese," added Christison. Osler (1894) very properly noted that such unrewarding gleaning comes from protracted searches in a restricted field.[18]

Claude Bernard said, "Medicine is not a science; it is a combination of sciences." Every important development in medicine serves to emphasize the importance of Bernard's observation. Empiricism, the experience and technical skills of surgeons, pharmacy, chemistry, experimental pathology, microbiology, and pharmacology, all play significant roles in the development of antiseptic and aseptic surgery, an interesting story too long for narration here.

Research

Since World War II, people everywhere have become deeply interested in many facets of research and their social implications. In consequence medicine is dealing with a continuously better informed public, which is as anxious to know that research is liberally supported as it is to learn the fruits of research. Several years ago, the husband of a former patient brought a friend of his to see me. The three of us chatted amicably in my office for some twenty minutes. Finally the visitor said to his (and my) friend, "Why are we here?" My friend replied, "We are here to talk about your problem." The visitor answered, "I have no problem." Retorted my friend, "Yes, you have." Inquired the visitor, "Well, what is my problem?" Said my friend, "It is your money; your money is your problem."

The upshot of this was that my patient called me later that afternoon to indicate his friend was contributing $100,000 to our research funds, which over the years have now grown to $300,000. About ten days after the first gift, however, my generous donor called to inquire, "Well, what have you discovered?" As all learn, who work hard at the pleasant but arduous game of research, and benefactors too, rewards are not gathered so quickly.

During my wanderjahr on the European Continent almost 40 years ago, I remember well a visit to the Kaiser-Wilhelm Research Institute, just outside of Berlin. Like a penniless little boy looking through a bakery window at delectables, I could only wish we could some day be fortunate enough to have in our country a research institute of this quality and magnitude. World War II succeeded very definitely in persuading our government, as well as our people, that research in all areas, including medicine, pays off handsomely. Current annual appropriations by our Congress for medical research are now in the area of a billion dollars.

In the midst of the depression years (1930-1939), world famous Surgeon William Mayo, of whom every Minnesotan is proud, and who for 32 years was a distinguished Regent of the University of Minnesota, persuaded the Legislature to provide the University's Medical School with an annual budget of $50,000 for research. To us at the time, it was like manna from Heaven, though more than 50 individuals shared in partition of the monies. Today, several investigators in our school receive more than $100,000 each for support of their own research. The largesse of our government has been magnificent; but in the end, it is the great interest, faith, and confidence of the public in research that makes all this possible.

In 1957, I was privileged to participate in a discussion on medical education at the University of Melbourne. No one having mentioned research, I thought it timely to bring it into the discussion, to which suggestion, a well-known surgeon in the area retorted, "Oh, that God-awful word!"

Even in certain circles closer to home, one hears said today, "There is too much research." "Give the medical school back to the students." "Researchers are a dime a dozen." These philosophies, however well intended, distort the situation badly. The contrary is certainly true. Only in an atmosphere of advancing knowledge is the student stimulated to do his very best. "Research, research, and more research," is the stirring admonition of that wise clinician, Paul Dudley White,[19] known to physicians everywhere.

We who are fortunate enough to enjoy the opportunities for research must take care not to assign these privileges second or third places in our thoughts. We must not be unmindful that experimental laboratories

Continued

for medical schools are essentially a product of this century.

The Doctor's Consulting Room

Prior to the cinema, radio, and television, the elementary school pupil was usually home evenings, hovering about a table in the family parlor near a small central source of light. Whatever defect the arrangement provided, it did afford the opportunity for the youngster to acquire a love of reading, emphasized by Anthony Trollope (1815-1882)[20] in this delightful admonition to college students: "With reference to the habit of reading, I make bold to tell you it is your pass to the greatest, the purest, and the most perfect pleasures that God has prepared for his creatures. Other pleasures may be more ecstatic. When a young man looks into a girl's eye for love, and finds it there, nothing may afford him greater joy for the moment: when a father sees a son return after a long absence, it may be a great pleasure for the moment: but the habit of reading is the only enjoyment I know, in which there is no alloy. It lasts when all other pleasures fade, it will be there to support you when all other recreations are gone."

The medical library is the doctor's consulting room. It is there physicians and investigators acquaint themselves with developments in the area of their own interest.

It is a thrilling and rewarding experience to enjoy the wonderful privilege of studying in the presence of great books, whose pages preserve the permanent and immortal legacy of great ideas. Many a student in the many disciplines of medicine who avail themselves of this privilege find their sights lifted and the nature of their dedication increased by contact with the inspiring stimulus of a fine library. Its atmosphere works silently upon the mind, uplifting the spirit and enlarging the student's vision, not unlike the stirring urge of the Divine.

When John Shaw Billings[21] made his famous address on our medical literature at the International Medical Congress held in London in 1881, he said: "There are 180,000 medical men scattered through the world, of which 65,000 are in the United States." Today the Director of the World Health Organization and the World Directory of Medical Schools[22] (1963) indicates there are 1,513,147 physicians in the world, of which number 234,294 are in the United States. There are today, therefore, more physicians in the United States than there were in the entire World in 1881. Billings added that for the calendar year 1879, the Index Medicus Catalogue of the Surgeon General's Office listed 1,643 books published throughout the world, of which 310 originated in the United States. There were 635 current journals on the shelves of the Army Medical Library (now the National Library of Medicine), when Billings reported upon his Survey in 1881. Today there are well in excess of 6,000 current medical periodicals, and most libraries like our own carry on their shelves at least 1,500 current numbers. Altogether in the biomedical field there are almost 9,000 medical serials.[23] It is quite obvious, therefore, that the medical sciences too have parallelled the population explosion in publication, all of which serves to point up the clinician's dilemma in trying to keep abreast of developments in his own field.

The brilliant German physiologist, DuBois Reymond,[24] more than 80 years ago emphasized the importance of historical approach to all studies, whether they concerned organizations, politics, language, or the sciences. The famous French medical historian, Emile Littre,[25] had some years previously pointed out that medicine must occupy itself with its history and develop a spirit of caring for monuments inherited from the past. Study of the history of medical disciplines provides scientists with an orientation they cannot otherwise acquire. Study of medical history enlarges the investigator's knowledge, broadens and strengthens his judgment, providing him with rich mines of the neglected. It also stimulates a respect and veneration for ideals and in the truest sense makes for better doctors. With the constant acceleration of the growth of knowledge, it is important that we not abandon the study of the lessons of the past. A study of medical history teaches the prospective doctor as well as the investigator how to separate wheat from chaff, while attaching humanistic values to the instruction.

A study of medical history is not to be thought of as delightful pastime for those contemplating the disengagement of retirement. Historical analysis is a most useful device in bringing into sharper focus the thoughts, considerations and theories which have advanced or retarded medical progress. You will be pleased to know that the medical school will presently establish a department of medical history which will add an important ingredient to the atmosphere of our school. As most of you are also aware, the medical school with a modest legislative appropriation and with important help from loyal friends in the community, is bringing to fruition a great medical library. I would like to believe that in the foreseeable future the medical profession of Hennepin and Ramsey Counties might come to enjoy its opportunities and privileges. Perhaps an appeal to the proper authorities might even overcome the current hurdle of available parking space!

The Surgeon and his Image

Every man needs to reassess his image periodically to note where he has been and where he is going. The minister of the Norwegian Lutheran Church in a small village in Becker County where I was confirmed as a boy 52 years ago, chose as his text of admonition to the confirmation class the well-known advice from Jeremiah: "Thus saith the Lord, Stand ye in the ways, and see, and ask for the old paths, where is the good way, and walk therein, and ye shall find rest for your soul." It is indeed sage advice. If a young surgeon knew exactly what he would like to make of his life, he might be well advised to repose judgment of how to arrive at such a goal in the hands of a competent person who could provide the needed counsel. I have known young surgeons who believe they can cultivate a large private practice and pursue simultaneously an academic career in research. Unfortunately either one of these areas is so demanding in time and energy expenditure that it takes all the strength and time anyone of us has to achieve in either domain. Life is a competitive process from beginning to end. The story of the race between the turtle and the hare certainly was no fable! During the intervening years I have thought many times of our minister's sober advice concerning stock-taking, but sadly, not often enough. One lives both by the calendar and by the clock. Perhaps one of the most important decisions anyone has to make is how to partition his time. Every man's foremost desire in life is to find that work which will prove soul-satisfying. It is the tyranny of the urgent present that robs many of us of our effectiveness. There are so many things to do; some we *have* to do; others we *want* to do; and not enough time in which to do them all.

Young surgeons, I know from experience, would rather operate than eat. As a group, they are men of action. Many academically oriented surgeons, believing themselves younger than the calendar suggests, continue spending most of their waking hours operating, thus often stifling their own laudable aspirations.

Though obvious evidences of operative skill characterize the accomplished surgeon, it must be recognized there are more important determinants for progress in surgery. Whereas there are those who say the most strenuous work the surgeon does is scrubbing his hands, in preparation to operate, yet anyone who has stood at the operating table for long hours knows what the toll is, not only in physical fatigue, but in mental acuity too. Whereas many a young surgeon may feel by continued application he will become a Paderewski or a Fritz Kreisler with the scalpel, there is more to surgery than this. The well balanced surgeon, conditioned to withstand physical and emotional strain, encompasses a large fund of factual knowledge with judgment and wisdom learned from experience, in addition to operative skill. My experience as a teacher suggests that of these qualities so important for the surgeon, operative skill, granted reasonable neuromuscular control, is probably most easily acquired. It has always been a source of continuing wonder to me to observe how quickly operative skills are acquired by young surgeons. Those who profess a desire to

Continued

continue the arduous climb up the academic ladder are ill advised to spend most of their waking hours in the operating room. Care must be taken not to become completely engulfed by the many magnetic and accessible attractions of the surgeon's life, including large pecuniary rewards. A more even allocation among study, research, teaching and thinking about problems of the craft is important and desirable, as they are all important components embraced in the minister's advice of frequent assessment of the direction in which anyone of us wants to go.

King James I,[26] of England, said: "I can make a Lord, but only the Almighty can make a gentleman." No man in his hurry to reach his goals can afford to neglect his associates, upon whom we are all very much dependent for counsel and criticism. An occasional critical look at oneself in the status-mirror of life advised by the Old Testament Prophet, can be of great benefit to all.

Thinking is some of the hardest work we have to do. It is probably far easier to go to the operating room and do another operation or two or to the library and consult another dozen or even a hundred more references. The state of diminishing returns is not solely a guideline for economists.

Changing Attitudes of Practice

With the prospect of control of infectious diseases almost in sight, need to accelerate global studies of population control is becoming increasingly evident. At the present rate of growth, the United States is doubling its population every 40 years, and by the year 2000 will be a country of 350,000,000 people. A few areas in the world are doubling population at considerably shorter intervals. Despite our increased capacity to produce food, the time will most certainly come when the world will be overpopulated unless interplanetary travel opens up new avenues for colonization or export.

Since 1880, there has been a four-fold increase in our population (U. S.) while our present physician increase has been only 3.6 times that of 1880. The public continues to clamor for more doctors, an ever increasing number of whom are going into specialties. The tremendous gains in medical knowledge through the agency of research will continue to attract larger number into research areas and specialty practice. The care of many types of illness today is essentially the responsibility of a specialist and the growth of specialism in Minnesota, as well as throughout our land, has been astounding since the end of World War II, and will undoubtedly continue because of medicine's increasing complexity. Trends toward more general adoption of the clinic idea, to which the Brothers Mayo lent such significant impetus, might well become the standard condition of practice everywhere in our country. Thoughtful integration of general practitioners and specialists into such clinic practice would provide all concerned with more satisfying conditions of work, appreciated by all as very important components of emolument. Such practices too would probably find favor with the public.*

Growth of Blue Cross and other insurance plans affect very materially the economic class of patients coming to university clinics throughout our country. Up until the beginning of World War II, there were in fact very few private patients in our wards. World War II changed all this. Most medical schools and ours too, under the leadership of Dean Howard, have made important strides in establishing controls which serve to remind the full time university clinician that his primary objective is not to cultivate a large private practice, which endeavor, if successful, would only succeed in stifling his professional growth.

Importance of Universities

With wise guidance from a number of medical school deans and university presidents, and with generous support from the profession and the people of Minnesota speaking through its legislative body over a period of more than four decades, increased stature has been and continues to be added to our School. If the University of Minnesota and its Medical School are to continue to hold their position and prestige in the intellectual and professional world, they will continue to need the whole-hearted support of this medical community. Some of you will remember the immortal words of the Poet Laureate John Masefield (1946) of England, who said: "There are few things more enduring than a university. Religions may split into sects or heresies; dynasties may perish or be supplanted, but for century after century, the university will continue, and a stream of life will pass through it, and the thinker and the seeker will be bound together in the undying cause of bringing thought into the world."[27] Liberal support of our schools, universities, and professional colleges by the public is a sound and probably the wisest investment for a bright and glorious future for any country.

---

*An interesting monograph entitled Planning for Medical Progress Through Education sponsored by the Association of American Medical Colleges has just appeared in print. This report may come to have as great an impact upon medical education as the Flexner Report of 1910. It stresses the team approach to medical problems, a thesis which this writer has espoused for many years (J Lancet 70:73, 1950).

The Computer — Not the Final Answer

The complicated structure of medicine which came into being as a consequence of the providential scientific period of fecundity of the post-war period served to emphasize the importance of research, which only in the second quarter of the present century has come to be fully appreciated. Today almost every hospital in a metropolitan medical school area desires an affiliation with the school, knowing that the fruits of research are reflected directly through all the activities of the Hospital, an impact that comes to be appreciated and felt by its board of trustees as well as by its patrons, the public.

Where the new scientific innovations will take us only the future and its experience will determine. Certain it is we shall continue to have more science and less empiricism in medicine, but in the age of the computer, competence, experience and dedicated devotion to his tasks are still the hallmark qualities of heart and mind of the good doctor and are so much appreciated by the sick. Sympathy, which is not to be found in a computer, continues to be the best solvent for the ills of man. William MacLure, beloved Doctor of Drumtochty, immortalized by Ian MacLaren in the Doctor of the Old School, is not a forgotten legend.[28] Medicine and love of one's fellow man are inseparable. A selfless devotion to his patients is still the guiding precept of a large segment of our profession here and everywhere. The late Carl Eggers, a New York thoracic surgeon, well-known to many surgeons here, paid a visit to his native Oldenburg shortly before his death and was asked to inscribe his name on the city's official ledger. After a moment's reflection, he wrote, "It is so easy to do good in the world and it makes one so happy."[29] Such is daily the great privilege of all of us and particularly so in medicine.

The late Walter B. Cannon,[30] who spent much of his childhood in St. Paul, relates in his autobiography, The Way of any Investigator, that his dying mother called him to her when he was ten years of age and said, "Walter, be good to the world." That the obedient son listened attentively and responded in a manner honoring medicine's finest traditions and with important benefits to medicine and mankind, every physician knows. I have the feeling that in the years ahead, with thoughtful evaluation of life's real satisfactions and rewards, we shall see a renewal of interest in and increasing evidences of an anxiety of our profession to improve our public image.

The future of medicine and surgery demands that while we strive to improve the science of our craft, we do not neglect the compassionate graces of sympathy, mercy and charity.

Maternal Mortality Studies

Maternal Mortality in Minnesota Due to Anesthesia*

Anesthesia continues to account for a significant proportion of the deaths in Minnesota due to obstetric causes. Sixteen such deaths occurred in the first 12 years of the state-wide Minnesota Maternal Mortality Study extending from 1950 to 1962, accounting for 5% of all deaths due to obstetric causes and for 9% of those considered preventable. Eleven of these 16 deaths were considered preventable. Among all causes of death, only hemorrhage, toxemia, and infection accounted for more fatalities in the preventable category.

It is of interest to note that death certificate information indicated anesthesia as the primary cause of death in only four cases. In the others anesthesia became evident as the cause only after the circumstances involved were investigated and the case considered by the Minnesota Maternal Mortality Committee.

A survey conducted in Minnesota by Knudsen, Rosenfield, and Lundgaard has shown that personnel adequately trained for administration or supervision of obstetric anesthesia is all too frequently not available. Of 174 hospitals offering obstetric services in the state, only 11 provided obstetric anesthesia supervised by anesthesiologists. One hundred four hospitals employed registered nurses, primarily on general duty, to give routine obstetric anesthetics.[1] This neglect is made evident by the results of this study which show that tragedies have occurred through errors made in large part because of inadequate training on the part of those responsible. In general, the choice of anesthetic was frequently wrong, the dosage administered was excessive, the patient was poorly prepared and inadequately supported, and resuscitative measures were delayed and inadequate. In none of the cases was the anesthesia supervised by an anesthesiologist. In two anesthesia was administered by untrained nurses, and in a third by a student nurse-anesthetist. Six were administered by registered nurse-anesthetists, one general anesthetic by an untrained physician, and the four spinal anesthetics and two regional blocks by the surgeon-obstetrician in each case (Table 1).

TABLE I
Obstetric Anesthesia Deaths in Minnesota, Type of Death, and Personnel Administering Anesthetic

		Anesthetist		
Type of Death	No.	Physician	R.N.A.	R.N.
Spinal	4	4		
Regional Block	2	2

Continued

While the study shows that the anesthetic was generally poorly chosen or poorly given, it is also clear that the death was frequently the end result of failure to follow basic principles of adequate patient work-up and conservative obstetric practices. Death from anesthesia was merely the culminating catastrophe that followed gross errors in management. For example, of six Cesarean sections performed, two were considered not indicated by the committee, and a third was a repeat section in a patient in whom the original section was not indicated. Of the other operative procedures performed approximately one half were either unindicated or were forceps procedures prematurely applied. In several instances obstructed labor was unanticipated because of inadequate pelvic evaluation, and in another case severe anemia was neglected, the patient dying of hypoxia when general anesthesia was applied by an untrained person.

The 16 fatalities included four from spinal anesthesia, two from regional block anesthesia, and six associated with aspiration; in four cases the principal precipitating cause of death was hypoxia.

Spinal Anesthesia

The principal problem in this group was the failure to appreciate the intolerance of pregnant patients for ordinary doses of anesthetic agents administered intrathecally. In all cases the dose of the anesthetic was excessive, varying from 120 mg. of procaine to 20 mg. of pontocaine, when maximum safe doses for the pregnant woman are considered to be 75 mg. and 8 mg. of each respectively. The Trendelenburg position was sometimes used, thus adding to the problem by increasing the height of the anesthetic level. Furthermore, in all cases there was complete neglect of provisions for checking anesthesia level, and measures for combatting vascular collapse and respiratory paralysis were lacking. It is most encouraging to note, however, that there have been no deaths from spinal anesthesia in obstetrics in the state since 1952.

Case Reports

Case #1

This patient was a 35-year-old para 7-0-0-7, for whom delivery by Cesarean section was planned because of previous section. She was anesthetized while in early labor with 120 mg. of procaine administered intrathecally and was given 2½ mg. of neosynephrine intramuscularly at the time of the application of the spinal, which was done by the surgeon. The patient was tipped in slight Trendelenburg position. No fluids were administered. No blood pressure determinations were done, and no check of the anesthesia level was made. A classical Cesarean section was performed with delivery of a normal 6½-pound infant. As the uterine wound was being closed the patient became gray, her pulse became impalpable, and she ceased breathing 20 minutes after application of the anesthesia. Blood loss had been minimal.

Case #2

The patient was a para 1-0-0-1 who was delivered of her first pregnancy by Cesarean section because of "outlet contraction." No record of pelvic measurements could be found. Cesarean section was carried out at 37 weeks' gestation with the anesthesia consisting of 20 mg. of pontocaine in 3 ml. of dextrose solution. As the skin scar was being excised, the patient became pale and then cyanotic. Respirations became very shallow and the pulse weak and thready. Twenty minutes after injection of the anesthetic, respirations ceased and the patient expired, despite application of artificial respiration and the administration of oxygen, coramine, and adrenalin.

Case #3

A 29-year-old primigravida requested that she be delivered by Cesarean section.

Because of this and because of a breech presentation, the physician agreed, although he considered the pelvic measurements normal. Anesthesia was produced by the injection of 18 mg. of pontocaine in 4 ml. of spinal fluid. The patient was kept flat for 10 minutes and then tipped in moderate Trendelenburg position. As the skin incision was being made the patient's blood pressure disappeared, and respirations ceased 15 minutes after the injection of the anesthetic. A rapid section was done and a living baby delivered, but efforts to resuscitate the mother failed.

Case #4

This patient was a 38-year-old para 6-0-1-6 whose course was complicated by hypertensive cardiovascular disease with superimposed toxemia. At 27 weeks' gestation she developed gross edema, blood pressure of 220/140, choked discs, and oliguria with 3+ albuminuria. Cesarean section was decided upon and anesthesia produced by injection of 150 mg. of procaine intrathecally. Almost immediately after application of the anesthesia her blood pressure was 60/0. She was given ½ ml. of adrenalin and 1 ml. of coramine, and terminally a blood transfusion was begun. Treatment failed and the patient was pronounced dead 30 minutes after injection of the procaine.

Regional Block Anesthesia

Both deaths in this category followed the performance of paracervical and pudendal blocks during labor in normal multiparous women. Each death occurred primarily as a result of the injection of toxic amounts of the anesthetic drug — 400 mg. of Cyclaine in one case and 1000 mg. of Xylocaine in the other — into a very vascular area. Resuscitative measures in both cases were somewhat delayed and inadequate.

The possibility of inadvertent intravascular injection must be borne in mind and guarded against in performing these blocks. It should also be pointed out that it is now known that an adequate volume consists of 7 or 8 ml. on either side for the paracervical and 5 ml. on each side for pudendal blocks done transvaginally. The current drugs of choice are Xylocaine, Carbocaine, or procaine in a 1% concentration.

Case #5

The patient was a 32-year-old para 1-0-0-1 who began labor spontaneously at 38 weeks' gestation after a normal prenatal course. After 3½ hours of uneventful labor, bilateral paracervical block was done with 10 ml. of 1% Cyclaine on each side, together with bilateral pudendal block with the same dosage. The total amount of the anesthetic injected was 40 ml. At this time the cervix was 7 cm. dilated, the patient's blood pressure was 128/76, and her general condition was good. Less than 15 minutes later she developed a generalized convulsive seizure and became cyanotic. Treatment consisted of oxygen and 5 ml. of sodium pentothal of unknown concentration injected intravenously. After two more convulsive seizures her blood pressure became unobtainable. Meanwhile delivery was accomplished by outlet forceps extraction. Despite administration of adrenalin, artificial respiration, and 2 grains of sodium amytal intravenously, the patient expired 25 minutes after injection of the anesthetic. Autopsy showed no anatomic cause of death.

Case #6

This patient was a 26-year-old para 1-2-0-2 who was admitted to a hospital at 25 weeks' gestation. The cervix was partially dilated and the patient was having irregular contractions. After 40 hours a Shirodkar procedure was carried out under spinal anesthesia produced by 50 mg. of Cyclaine. However, the patient went into active labor and delivered 3½ hours after surgery. Pudendal and paracervical blocks were carried out, using a total of 100 ml. of 1% Xylocaine. Ten minutes after delivery the patient developed generalized convulsive seizures and vasomotor collapse and lost consciousness. The convulsions were controlled after two hours with sodium pentothal anesthesia, but administration of blood, intravenous fluids with vasopressors, and oxygen failed to correct the vasomotor collapse. The patient died nine hours post partum. Autopsy was negative except for some evidence of intrauterine and urinary tract infections.

Deaths Due to Aspiration

The six deaths associated with aspiration illustrate a number of points.

Continued

Three resulted from mechanical obstruction of the trachea and/or bronchi while three resulted from overwhelming pulmonary edema due to aspiration of liquid gastric contents as described by Mendelson.[2] These deaths show that oral intake of liquids as well as solids during labor can be dangerous if general anesthesia should subsequently be required.

Treatment of the effects of aspiration is unsatisfactory. Administration of oxygen under positive pressure and the use of steroids have been advocated, but in many cases neither is adequate. It has also been shown that bronchoscopy is frequently of little help, particularly after aspiration of liquid stomach contents.

The best "treatment" is clearly preventive. It is essential that food and fluids be withheld during labor if there is a possible need for subsequent general anesthesia. It should be borne in mind that gastric emptying time may be indefinitely prolonged during labor. If operative delivery becomes necessary despite the fact that the patient is known to have liquid or solid food in her stomach, some form of conduction anesthesia should be used. Vomiting can still occur but, if the patient is awake with intact reflexes, significant aspiration will not occur. If there is no alternative to general anesthesia, intubation of the trachea should be carried out preoperatively by someone experienced with this technique. It has been shown, however, that even intubation can be dangerous, as instances of vomiting and fatal aspiration under the anesthesia given for the purpose of intubation have been reported.

This group again illustrates instances of poor selection of anesthetic agents (nitrous oxide for a midforceps extraction, for example), poor technique with inadequate depth of anesthesia before operative manipulations were begun, and inadequate patient support and resuscitation. Many gross errors in obstetric management are also apparent. One death resulted from the administration of trichlorethylene by a nurse. This agent is meant to be used only for analgesia and to be self-administered by the patient.

Case #7

This patient was a 36-year-old primigravida with an incompletely measured pelvis. She was five feet tall and weighed 250 pounds. Spontaneous onset of labor occurred at 42 weeks' gestation. During a prolonged desultory labor of 40 hours duration, the fetal heart tones disappeared. Three hours later the cervix was completely dilated, and the fetal head was at the level of the ischial spines in the right occipitotransverse position. A decision was made three hours later to deliver the patient by midforceps extraction, and she was anesthetized with nitrous oxide by a nurse-anesthetist. As the forceps were being applied, the patient developed laryngeal spasm and became deeply cyanotic. An unsuccessful attempt was made to insert an airway. Administration of oxygen by bag pressure failed because of the laryngeal spasm. The patient vomited, developed generalized convulsive seizures, and expired 20 minutes after the beginning of the attempted forceps delivery. Up to five hours before delivery, the patient had been given liberal amounts of fluid orally.

Case #8

The patient was a 22-year-old primigravida who was known by x-ray pelvimetry to have borderline measurements both at the inlet and mid-pelvis. Because of this, labor was induced with intravenous oxytocin at 38 weeks' gestation. After a six-hour first stage of labor, progress ceased. After four hours of second-stage labor an attempted midforceps rotation and extraction under ether anesthesia failed. During this process the patient vomited. Cesarean section was then carried out under pentothal anesthesia administered by a nurse-anesthetist. Prior to administration of the anesthetic the patient was coughing, and during the procedure she vomited and aspirated liquid bile-stained material. The trachea was aspirated with a catheter, but the patient remained cyanotic. At the conclusion of the operative procedure, she was cyanotic with a pulse rate of 160, respirations of 45, and physical evidence of consolidation in both lungs. She then developed peripheral vascular collapse and died four hours post partum. Autopsy showed marked bilateral hemorrhagic pulmonary edema.

Case #9

This patient was a 28-year-old para O who went into labor spontaneously at term. The first stage of labor was some 34 hours in duration and was characterized by administration of excessive medication for sedation and inadequate treatment for uterine inertia. The patient had frequent emeses and was fed regularly. She was seen in consultation by an obstetrician who found the cervix to be completely dilated with the head at station plus 1 in the right occipitotransverse position. On his instructions the patient was anesthetized by a nurse-anesthetist with 50% cyclopropane for one minute, followed by 30% with a gradual change over to ether. After six or seven breaths of ether, forceps application was made and an attempted rotation was carried out. The patient promptly vomited. She was inadequately suctioned and no intubation was done. She was re-anesthetized and delivered. Post partum she developed fever of 103°, cyanosis, blood pressure of 90/50, pulse rate of 160, and respiratory rate of 50. Physical examination and chest x-ray showed evidence of pulmonary edema and atelectasis. Despite digitalization and treatment with antibiotics, hydrocortisone, and oxygen, the patient died with continuing respiratory difficulty 44 hours after delivery.

Case #10

This patient was a 21-year-old para 0-1-0-0. No adequate pelvic evaluation was done, although simple flat films of the pelvis were taken, which indicated probable inlet and mid-pelvic contractions. The patient went into labor at term with the fetal head floating. After 24 hours of hard labor the cervix was completely dilated, and an attempt at high forceps extraction was made under ethylene anesthesia. The delivery attempt failed, and in the process the fetal heart tones disappeared. The patient was allowed to recover from the anesthesia, after which she was given oral fluids. After 6½ hours of second stage and a total labor of 31 hours, a difficult midforceps extraction of a stillborn infant was done under ethylene anesthesia of 30 minutes' duration. The anesthesia was given by a student nurse-anesthetist. During delivery the patient vomited twice, and following the second episode she remained cyanotic despite administration of oxygen and aspiration of the mouth and the pharynx. Her blood pressure after delivery was 80/0. She remained cyanotic and in shock. Evidence of pulmonary edema appeared, and death occurred four hours after delivery.

Case #11

A 29-year-old para O was subjected to laparotomy for an ectopic pregnancy under pentothal-curare anesthesia administered by a nurse-anesthetist. Laparotomy was begun three hours after the patient had consumed some soup and tea. When the abdomen was being closed, it was noted that the patient was not breathing, and she promptly died despite efforts at resuscitation. There was no evidence of vomitus in the mouth or pharynx, but autopsy showed the bronchi and trachea to be filled with thick mucoid material containing numerous food particles.

Case #12

This patient was an 18-year-old para O who was admitted to the hospital in early labor at term. Four and one-half hours after admission the cervix was thought to be completely dilated, and she was moved to the delivery room where trichlorethylene was administered with contractions by a nurse untrained in anesthesia. This was continued for an hour and 45 minutes with a Duke inhalator set at "a little past 5." The patient then appeared to be under deep anesthesia. Contractions ceased and she retched several times. She then became cyanotic, had several generalized convulsions and died in about 10 minutes. At autopsy the trachea and bronchi contained aspirated stomach contents, and there was complete atelectasis of much of both lungs. It was known that the patient had not taken any solid food for more than 12 hours before delivery, but the records did not indicate whether she had been given liquids.

Deaths Due to Hypoxia

In each of these cases the patient was in poor preoperative condition for general anesthesia. Complications included anemia, hypovolemia, and restriction of respirations due to previous chest surgery or obesity. In general the choice of anesthetic was poor and it was poorly administered. It is known that patients with restricted alveolar ventilation are prone to

Continued

the development of respiratory acidosis. Pentothal and curare, which were used in three of the four cases, may further depress respirations, and a vicious cycle develops from which the patient cannot be recovered. The anesthetic risk in these patients is particularly high, and expert handling is essential.

Case #13

This patient was a 21-year-old para 2-0-0-2 whose prenatal course was complicated by toxemia and anemia. On admission to the hospital her hemoglobin was found to be 6.9 grams per 100 ml. The anemia was not treated. Spontaneous onset of labor occurred, and the first of a set of twins was delivered after 2½ hours of labor. Despite stimulation with pituitrin the second twin was not delivered until 15 hours later. The placenta was then retained and after two hours manual removal was attempted under open drop ether anesthesia administered by a nurse who had no anesthesia training. As the operative procedure was being completed the patient stopped breathing. Manual artificial respiration was done, oxygen was administered, and terminally whole blood was pumped in; but there was no response and the patient was pronounced dead one-half hour later.

Case #14

This patient was a 42-year-old para 0-0-2-0 who had a 15-year history of treatment for pulmonary tuberculosis, including oleothorax. She had a marked reduction of pulmonary function with a vital capacity of 1200 ml., plus electrocardiographic and physical evidence of right ventricular strain and hypertrophy. After she had developed signs and symptoms consistent with a diagnosis of early ectopic pregnancy, exploratory laparotomy was planned. She was anesthetized by a nurse-anesthetist with pentothal-curare and promptly became cyanotic. Intubation was carried out and the patient was given some isuprel intravenously. Bag breathing was instituted, but within 15 minutes the blood pressure had dropped to 80/54. Despite administration of blood, 2 ml. of Tensilon and atropine intravenously, the patient died an hour and 20 minutes after the anesthesia was begun. No surgery was performed. Autopsy showed an ectopic pregnancy involving the left tube and dilatation and hypertrophy of the right ventricle. The trachea and bronchi were clear.

Case #15

This patient was a 28-year-old para 2-0-0-2. Classical Cesarean section was carried out at 41 weeks' gestation without indication. The patient had been having false labor for a week and was edematous, but the findings were otherwise normal. Premedication consisted of 50 mg. of demerol and grains 1/150 of atropine intravenously. The anesthesia as administered by a physician who had no anesthesia training and consisted of 2½% pentothal with curare and nitrous oxide-oxygen in a 2-1 mixture. The duration of anesthesia was one hour. Immediately after the surgery was completed respiratory failure developed. Following this the patient remained cyanotic with a pulse rate of 130 to 160 and blood pressure of 170/100. She was given oxygen and two doses of Tensilon of 1 ml. each intravenously. One hour post partum her blood pressure fell to 80/60. She vomited several times and developed convulsive movements and restlessness. She died in respiratory failure nine hours post partum.

Case #16

This patient was a 44-year-old para 7-0-3-6. She was very obese with a weight of 210 pounds and a height of four feet, nine inches. She was also hypertensive. At 24 weeks' gestation she developed strangulation in an incisional hernia. Surgery was carried out for reduction of the hernia under sodium pentothal anesthesia administered by a nurse-anesthetist. Immediately after the administration of the pentothal the patient became cyanotic and remained so despite intubation and artificial respiration with a bag. The surgical procedure was one hour and 20 minutes in duration. The patient's color was never good, and she seemed to be "wet" despite aspiration. There was no vomiting. She was given a total of 875 mg. of pentothal and 175 units of curare. She was also given 2 ml. of Tensilon intravenously just after the surgery was begun and again just before it was finished. As the dressings were being applied, the patient's blood pressure disappeared and attempts at resuscitation were unsuccessful. Autopsy showed cardiac hypertrophy with minimal pulmonary edema and atelectasis.

Conclusions

Obstetric deaths in Minnesota due to anesthesia resulted in large part because of ineptness in the selection and/or administration of the anesthetic agents. In the majority of cases, errors in obstetric management including performance of unindicated operative procedures led to administration of anesthesia under unfavorable conditions.

Fatalities resulting from spinal anesthesia appear to be a thing of the past. The last such death occurred in 1952. Deaths from vomiting and aspiration can be further reduced by maintaining awareness of the dangers of general anesthesia in patients who do not have empty stomachs. More widespread availability of experts in anesthesia is needed, particularly for the poor risk group of patients.

Famous Preface

In his preface to the English dictionary, Samuel Johnson, 1755, stated, "I am not yet so lost in lexicogiphy as to forget words are the daughters of earth and that things are the sons of heaven. Language is the only instrument of science and words are but the signs of ideas."

In his letter to the Right Honorable Earl of Chesterfield after he had finished his dictionary, he stated, "Is not a patron, my lord, one who looks with unconcern on a man struggling for life in the water, and, when he has reached ground, encumbers him with help? The notice which you have been pleased to take of my labors, had it been early, would have been kind; but it has been delayed till I am indifferent, and cannot enjoy it; till I am solitary, and cannot impart it; till I am known, and do not want it.

"I hope it is not very cynical asperity not to confess obligations where no benefit has been received, or to be unwilling that the public should consider me as owing that to a patron, which providence has enabled me to do for myself."

Men have lost sight of distant horizons. Nobody writes for humanity, for civilization; they write for their country, their sect; to amuse their friends or annoy their enemies. — George Norman Douglas

Anturane®
brand of
sulfinpyrazone

Dosage
Anturane, brand of sulfinpyrazone, is available as white, scored tablets of 100 mg. Initially, give half a tablet 4 times daily with meals or milk, increasing in one week to one tablet q.i.d. Increase to two tablets q.i.d. if necessary, and reduce if possible to as low as half a tablet q.i.d. after control. Continue through acute attacks, which can be concomitantly treated with phenylbutazone.

Patients on other uricosurics may be transferred to this drug at full dosage.

Contraindications
Active peptic ulcer. Salicylates and citrates antagonize the drug's action and are contraindicated for concomitant use.

Warning
Use with caution in pregnant women.

Precautions
Keep patients under close supervision and make periodic blood counts. Use cautiously in patients sensitive to pyrazoles, in patients with histories of peptic ulcer, and in conjunction with sulfa drugs, the sulfonylurea hypoglycemic agents, and insulin, the actions of which may be potentiated.

In mobilizing urate deposits, the drug may precipitate acute attacks of gout, urolithiasis, and renal colic, especially in the initial stages of therapy. Ensure adequate fluid intake and alkalinize the urine. With renal impairment, test renal function periodically.

Adverse Reactions
The most frequent are upper gastrointestinal disturbances. The drug may activate peptic ulcer. Rash occurs infrequently. Although not reported to date, blood dyscrasias are a possibility.

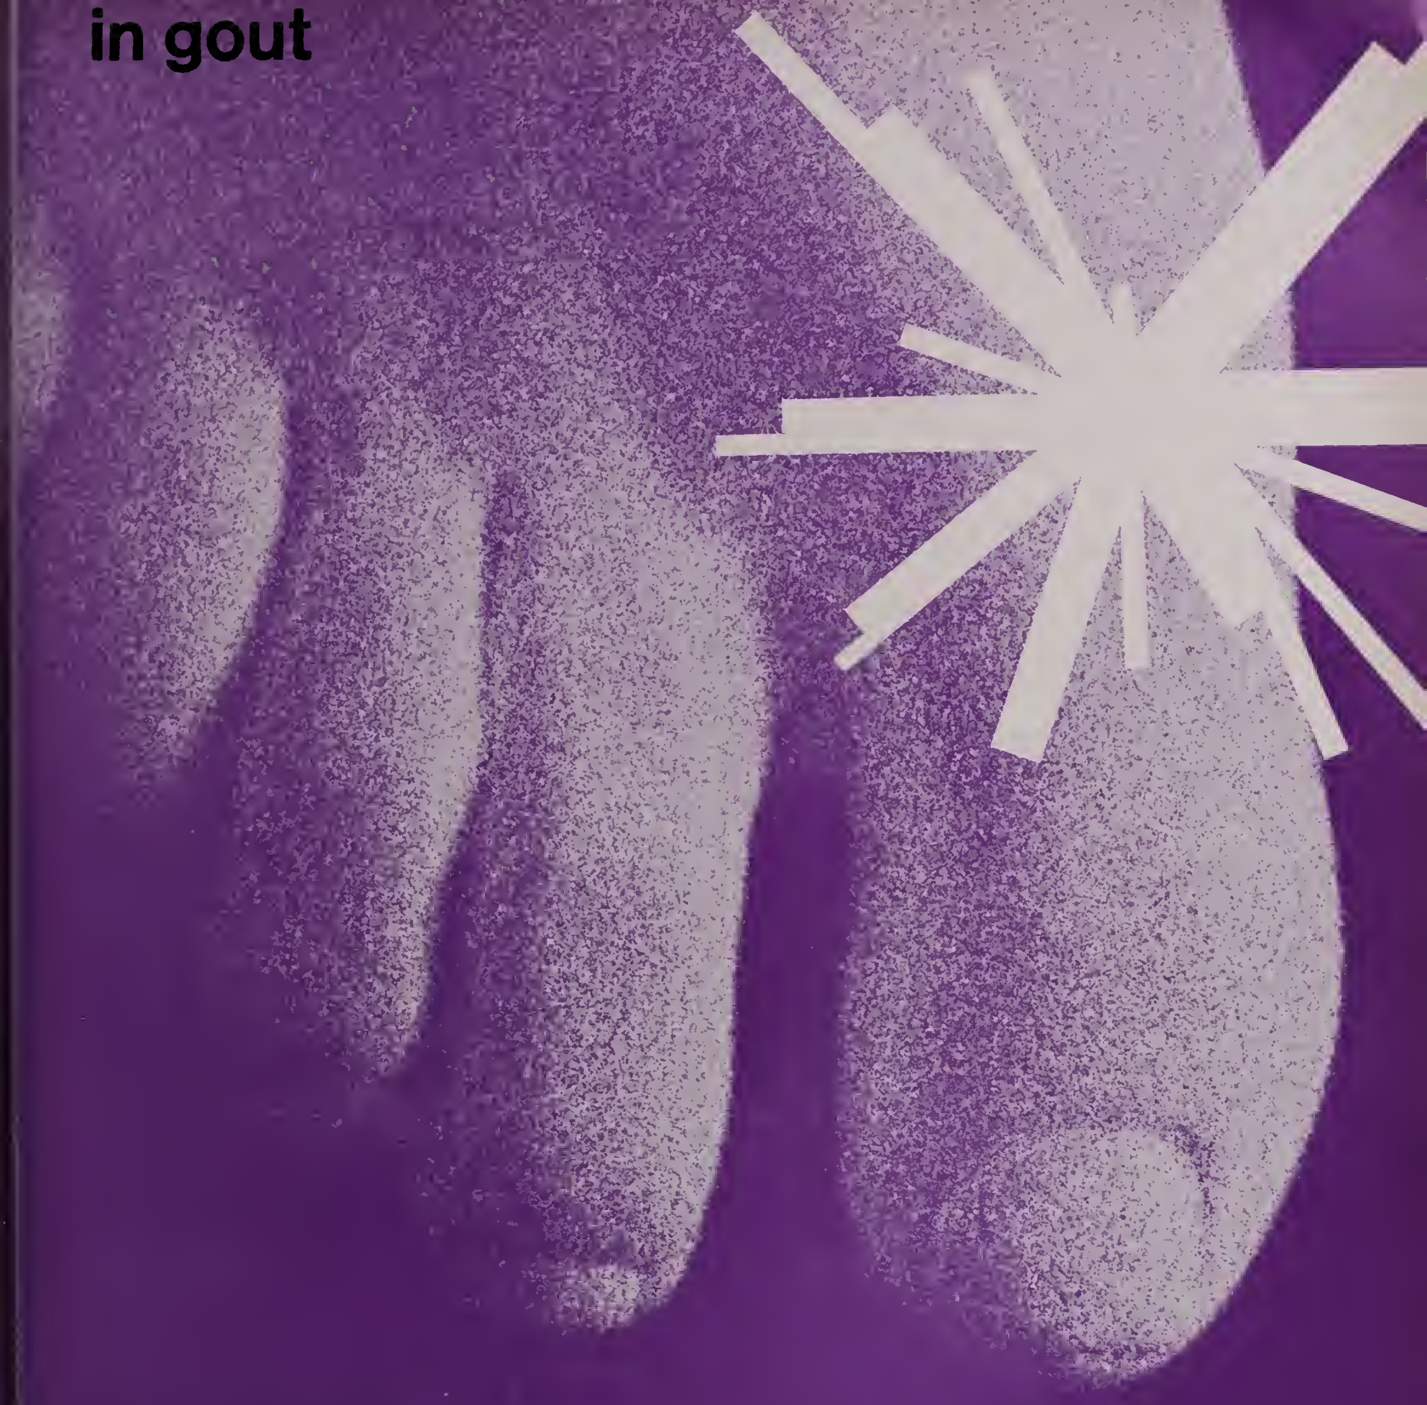
in gout



Anturane®

brand of sulfinpyrazone

"the most effective and best tolerated of the currently available uricosuric agents for the control of gout."*

Geigy

Anturane, brand of sulfinpyrazone, was developed in the Geigy laboratories. Its pharmacologic activity is limited almost exclusively to increasing the urinary excretion of uric acid. For this reason, it is a drug of choice in chronic tophaceous gout and acute intermittent gout. It is not intended for relief of acute attacks of gout.

In most patients, the drug rapidly reduces serum uric acid levels to normal. This not only prevents new tophi but also mobilizes and promotes the excretion of urates already in the tissues. The reduction of tophi and periarticular crystals results in more mobile, less painful joints.

Anturane, brand of sulfinpyrazone, materially reduces the number and severity of acute attacks of gout. It may also be used to counteract hyperuricemia induced by certain diuretics.

Because of its potency, the drug is often effective in patients refractory to other uricosuric agents. Patients can usually be maintained indefinitely on it without cumulative effects or development of tolerance.

Photographic Contest

The Editors of Minnesota Medicine, in collaboration with the Doctors' Photographic Society of Minneapolis, take pleasure in announcing a monthly photographic contest. The contest is to promote an interest in photography in the medical profession. First prize each month will be publication in full color of the winning picture in Minnesota Medicine.

The following rules will govern the conduct of the contest:

1. Only doctors of medicine are eligible to submit pictures, and the picture must have been taken or composed by a physician.
2. Each contestant may submit not more than two pictures each month.
3. Only color transparencies, 35 mm. to 2¼", can be considered.
4. Each slide should be labeled with the maker's name, address, and the identifying title.
5. Slides should not be mounted on glass, but can be protected in plastic sleeves or envelopes.
6. Each entry must be accompanied by a self-addressed, stamped envelope if return of the picture is desired. Returns will be made shortly after the close of the contest each month. The winning photograph will be retained but will be returned after it has been used.
7. The deadline date for entry will be the 10th of each month and the winner of each month's contest will be announced in Minnesota Medicine in the subsequent issue. The date of publication will be three to six months in advance.
8. There will be no limitation on subject material except as indicated in item 10.
9. Model releases will be requested of winners where appropriate.
10. Judges will be selected by the editors of Minnesota Medicine and the Doctors' Photographic Society. The judges will be guided by the precepts of the Photographic Society of America, and winners will be based on appropriateness, interest, impact, and technical excellence.
11. The editors of Minnesota Medicine and the Doctors' Photographic Society cannot be responsible for entries lost or damaged, but every effort will be made to protect submitted pictures.

Your pictures are hereby invited. Please submit pictures to:

History of Medicine

Robert Koch

(1843-1910)

> *"Before microscopic forms can be regarded as the cause of contagion in man they must be found constantly in the contagious material, they must be isolated from it and their strength tested."*
> —*Jacob Henle*
> *Patholotical Researches, 1840*

Robert Koch initiated modern bacteriological technique, elevating bacteriology into the position of a separate science. To him we owe the main basis of the technique by which diseases are now studied.

Born into a large impoverished German family, it appeared certain that Koch would be obliged to learn the shoemaker's trade. However, the family's financial condition improved to the extent that he was able to go to Gottingen to study medicine, where he became a pupil of the great Henle. After graduation, he settled in the town of Rachwiz as a general practitioner. He served in the Franco-Prussian war, following which he resumed practice as district-physician of Wollstein.

His career in research began in 1872 when his wife gave him a birthday present of a microscope. This obscure physician, without university or research institute affiliation, worked not in a laboratory, but in his own home. Located in an agricultural region where anthrax was common among sheep and cattle, it was in the microscopical study of this disease in rabbits that Koch made his first great discovery. "He it was who first laid bare the natural history or life story, of the anthrax bacillus, and showed how to grow the bacillus, and how to obtain it unmixed with other organisms in 'pure culture' . . . Koch showed how to grow the organisms on solid media. He showed also that different organisms took up different dyes from a solution, so that they could be distinguished one from another by observing what color they took on when dyed with different chemicals."[1]

At the end of ten years of research Koch was the . . . "first to work out the complete life-history and sporulation of a bacterium. At that time bacteriology was a department of botany, and Ferdinand Cohn, the great botanist of Breslau, was the leading authority on microscopic plants. Whoever wanted information on the parasitism of Algae and Fungi, applied to Ferdinand Cohn. In the spring of 1876, Koch wrote to Cohn: 'After many vain attempts, I have finally been successful in discovering the process of development of the anthrax bacillus. After many experiments, I am able to state the results of these researches with sufficient certainty. Before, however, I bring this into the open, I respectfully appeal to you, esteemed Herr Professor, as the foremost authority on bacteria, to give me your judgment regarding this discovery.' "[2]

Cohn not only agreed to see Koch himself; he also invited some leading investigators of that day to witness the new methods. Among them was Professor Conheim, the foremost experimental pathologist of Europe. So down to Berlin came the unknown country doctor with his cultures of anthrax, a little doubtful himself as to whether or not he was on the right track. Professor Conheim was greatly impressed with Koch, hailing his

Continued

discovery as one of the most brilliant in the world. He had grasped the significance of it at once. Through his efforts Koch became a member of the Imperial Sanitary Commission in Berlin. In that way he could continue his research there. "Koch's accomplishments wrought a transformation in the health department . . . and in 1881 he dwarfed all his associates by his scheme of spreading liquid gelatin with meat infusion on glass plates, thus producing transparent solid media for pure cultures. This poured-plate method may be regarded as Koch's greatest single achievement, for there is no other method by which the bacteriologist can grow, isolate and recover pure cultures."[3]

History of Medicine in Wright County*

Stephen J. (or J. S.) Wooster, occasionally spelled **Worcester,** came to Cokato in 1882 and practiced there through 1886. In August, 1882, when his arrival in Cokato was expected, the newspaper called him "Dr. Worcester from Wyzata." Dr. Wooster was a charter member of the Crow River Valley Medical Society (the forerunner of the Wright County Medical Society) when it was organized in 1883 and was a signer of its articles and by-laws. He was elected treasurer at the meeting in October, 1883.

In 1886 he is listed in Cokato as the only physician. He was a graduate of the College of Physicians and Surgeons, Keokuk, Iowa in 1882, was licensed in Minnesota October 1, 1883 and registered in Wright County on December 10 of that year. The "Official Register of Physicians, Minnesota, 1883-1890" state that he "removed from the state;" this must have happened not later than 1890. He must have returned to Minnesota as he is listed in Annandale in 1898 and 1900 and later was with his son in Rockford.

C. A. Wright, apparently started practice in Howard Lake in 1875. His card appeared first in the *Wright County Eagle* on February 3 of that year; he presents himself as an "homeopathic physician and surgeon; all calls promptly attended to." Medical directories list him there through 1893 (but no longer in 1896). Dr. Wright owned a 210 acre farm — on the Watertown Road on the Crow River, halfway between Delano and Watertown. He offered it for sale in February, 1884.** In April of that year he was elected surgeon of the Goodsell Post No. 86 G.A.R. at Howard Lake.† It seems he was a great hunter as the papers mention several times his trips to the prairies (1884 and 1885) and at one of these (November, 1885) he claimed to have killed five deer. In December, 1885 a news item mentions that he and a couple of other men were getting ready for an extended trip to California via Kansas.‡ Nothing more is known about him. There is no information of his background, where he came from or where he moved to.

Frugality. Make no expense but to do good to others or yourself; i.e., waste nothing.
— Benjamin Franklin

Physicians, Nurses Often Fail to Communicate, Says Professor of Nursing

The nurse and the physician work side by side in the hospital but frequently fail to understand one another.

The ultimate loser in any failure of doctor-nurse communication is the patient. If, for example, the nurse does not fully comprehend a doctor's orders regarding a patient, the patient suffers. If a doctor does not understand the nursing hierarchy in a hospital, he may issue orders which by their very nature are difficult for the nursing staff to carry out — and again the patient suffers.

"Nurse-Physician Communications in the Hospital" was the subject of a special program recently at the 114th annual convention of the American Medical Association. Sponsor of the session was the AMA Committee on Nursing.

"Communication difficulties appear to be related to the social structure of hospitals," said one of the speakers, Luther Christman, Ph.D., R.N., associate professor of nursing at the University of Michigan, Ann Arbor.

"For instance," he said, "vast educational differences exist between doctors and nurses. Training and education create vital differences in the way physicians and nurses see events in the hospital. In addition, the physician remains oriented to continued learning through postgraduate education, while the nurse's formal education usually stops the day she leaves training." In time, Dr. Christman added, the trend toward baccalaureate education and graduate training for nurses may reduce the educational gap.

As other critical areas of communication difficulty due to hospital social structure, he cited:

1. The various and often highly specialized technical languages of subgroups in the hospital. Nurses may lack the training to understand a highly technical order, but may be hesitant to ask for clarification. "People do not like to admit they do not understand, particularly if the communicator is a superior . . . thus the physician may leave the ward believing he has communicated only to be chagrined, and perhaps irked, when he finds this is not the case." Dr. Christman noted the best trained nurses are often placed in administrative positions where they contribute least to doctor-nurse understanding.
2. The differing career patterns of the two professions. Physicians are often self-employed and self-directing. Nurses are employees subject to control from the hospital medical staff, hospital administration, and nursing administration. If physicians assume that nurses have the same degree of self-direction as themselves, misunderstanding may result.
3. Socioeconomic class differences between members of the two professions. Physicians usually enjoy considerably larger incomes than nurses, permitting a different style of life that seldom brings them into social contact with members of the nursing staff. Also, physicians traditionally come from families with professional and business backgrounds while nurses most often come from working-class and lower-middle-class families; both groups take their social perspectives into training with them.
4. Sex differences, since most physicians are men and most nurses women. Normal cultural patterns of presumed male dominance and superiority are probably in effect during doctor-nurse professional contacts.
5. Clashes over power. The physician's accustomed position as a power unto himself in his office, and his intense preoccupation with the clinical problems of his patients in the hospital, may bring him into conflict with nurses when he is expected to share power in the complex organizational structure of the hospital.

"The hospital social structure can be made to help rather than hinder communication, if doctors and nurses cooperate in changing it," Dr. Christman said.

Among changes he recommended to facilitate physician-nurse understanding:

1. The employment of non-nursing personnel to perform non-professional administrative duties now being carried out by nurses, thus releasing many of the best educated nurses for patient care.
2. Improve the salaries of nurses. Physicians could help improve the climate between themselves and nurses if they actively supported moves for better nursing salaries.
3. Fostering of liaison committees between state medical societies and state nurses associations.

Continued

4. Organizing joint clinical workshops on state or district levels.
5. Sponsoring of joint research in improvement of patient care.

Also speaking on the program yesterday was Barbara Bates, M.D., Department of Medicine, University of Kentucky, Lexington.

Dr. Bates told of actual research done on the problem of nurse-physician communications by means of a questionnaire circulated to doctors and nurses in a university teaching hospital.

Each person receiving the questionnaire was asked to report specific incidents concerning the behavior of members of the other group, and how such incidents affected the patient.

Of the 839 replies received from nurses and the 475 from physicians, a total of 367 involved communication by either a doctor or nurse. Some incidents were examples of poor communication where the patient suffered, others were reported as illustrations of good doctor-nurse communication helping the patient.

Moderator of a reacting panel discussion was Edward G. Benz, R.N., director of nursing at Embreeville State Hospital, Embreeville, Pa.

Partnership Disability

We plan to publish an article on "Partnership Retirement." The theme of this article is that retirement provisions, beyond the value of the retired partner's assets and accounts receivable, are basically the financial responsibility of the individual partner, and not the collective responsibility of the partnership.

Restating our premise, that the primary goals of a partnership should be higher quality of practice and maximum ease of practice, there is little logic for a partnership assuming the economic responsibility for either retirement or disability of its members. On the contrary, the ill-advised assumption by a partnership of these financial responsibilities may prove to be a complete financial impossibility.

We have read proposals by various proponents of funding disability through a partnership. These proposals vary all the way from a few months of protection to lifetime indemnity. Some of the long-term proposals advocate funding by insurance after a certain period of time.

Simply analyzed, long-term disability protection funded out of earnings is economically impossible since it must come from reduced earnings of other partners. Disability insurance purchased through the partnership is impractical since there is no tax advantage and each partner ends up paying his own cost. The major disadvantage of an insured plan is that several partners may end up with insurance in amounts and types, and with companies that would not be their individual choice in a personal program. In our opinion, a disability provision which will provide a smooth transition for the disabled partner until *his* insurance program takes over, and one which gives realistic recognition to the financial equity of the disabled partner and the earnings of the remaining partners, is the only valid approach to partnership disability.

The most common disability arrangement in a partnership is one which provides guaranteed earnings continuation for the first three to twelve months of disability. For example, three months at 100%, three months at 75%, three months at 50% and three months at 25%. At the end of this period, the disabled partner's status must be appraised. If disability appears to be long-term or permanent, the disabled partner's interest will generally be terminated. If it appears he will return to work in a reasonable period, his earnings can be "suspended" until he returns.

Whatever the final specific provisions, partnership indemnity must represent realistic interim earnings, to be replaced by the disabled partner's individual insurance program for long-term protection.

An excellent principle to adhere to in discussing problems such as this in a partnership is to place yourself in the position of both the disabled and the remaining partner and consider all contingencies. If a proposal can survive this test and all partners agree to the logic of being the payor as well as the recipient, then the plan may have merit.

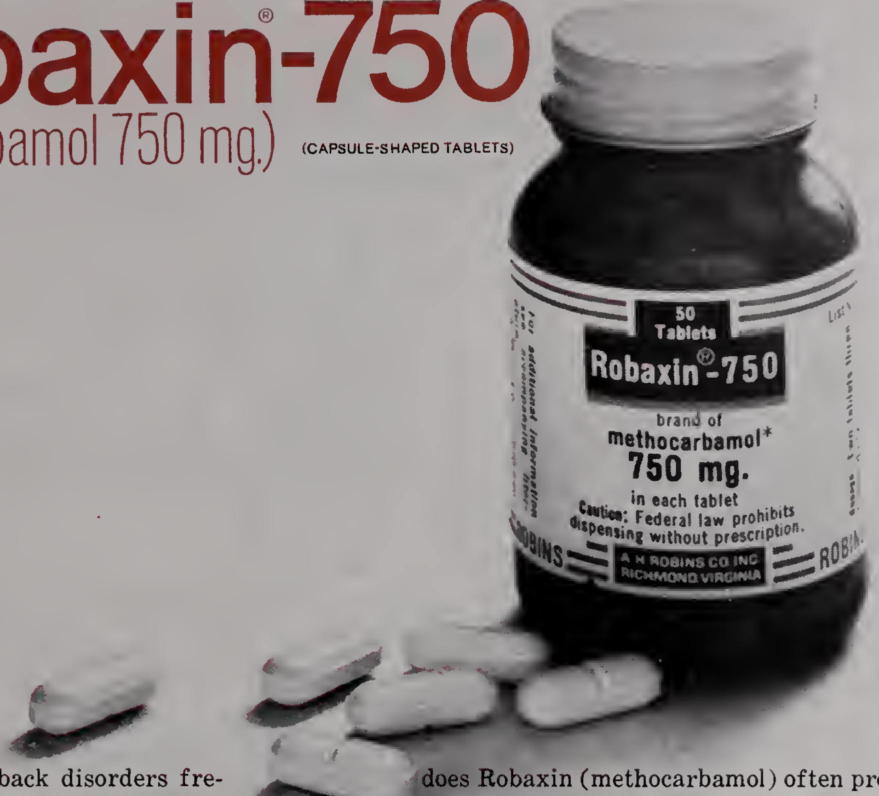
Doctors like fees no doubt — ought to like them; yet if they are brave and well-educated, the entire object of their lives is not fees. They, on the whole, desire to cure the sick; and, if they are good doctors, and the choice were fairly put to them, would rather cure their patient and lose their fee than kill him and get it.
— John Ruskin

and Robaxin®-750

(methocarbamol 750 mg.) (CAPSULE-SHAPED TABLETS)



It has been noted that low-back disorders frequently "... are caused by truly mechanical conditions which yield to conservative treatment."[1] Basic to this conservative treatment are bed rest, a board for the bed, and applied heat. In addition, a good muscle relaxant is often helpful, as "... muscle relaxants are useful in chronic as well as acute low backaches."[4]

Robaxin (methocarbamol) has relieved spasm and pain in cases where the patient "had not responded to conservative measures prior to drug therapy."[6] A 100-patient study showed that Robaxin provided greater relief of muscle spasm for a longer period of time without adverse reactions "than any other commonly used relaxants...."[6]

A well-tolerated[7] skeletal muscle relaxant with "specificity of action,"[7] methocarbamol leaves normal muscle tone unaffected. Moreover, there is little likelihood of sedation[7]—a considerable advantage for the patient who must remain active and alert on his job.

Significantly, clinicians advise using a muscle relaxant "early and in adequate dosage."[8] In this regard, Robaxin (methocarbamol)—*particularly in the 750 mg. dosage (2 tabs. q.i.d.)*—offers optimal therapeutic benefits without a significantly increased incidence of side effects. And just as it works well as part of the basic regimen for low-back pain, so also does Robaxin (methocarbamol) often provide muscle relaxation in such conditions as musculoskeletal injury, chronic neurological disorders, and orthopedic situations.

BRIEF SUMMARY—Robaxin (methocarbamol) Tablets: Contraindicated in hypersensitive patients. Side effects (light-headedness, dizziness, drowsiness, nausea) may occur rarely, but usually disappear on reduced dosage. Hypersensitivity reactions develop infrequently.

ALSO AVAILABLE: Robaxin® Tablets (methocarbamol, 500 mg.) Robaxin Injectable (methocarbamol, 1 Gm./10 cc.)

Robaxisal® (methocarbamol with aspirin) and Robaxisal-PH Tablets (methocarbamol with Phenaphen®).

Winning Essay

The Advantages of Private Medical Care

James Kramer
Holy Trinity School
Rollingstone, Minnesota

This essay won second national prize of $500 in the 1965 Association of American Physicians & Surgeons Essay Contest.

When the proposed plan of medicare was first exposed to me, I realized that I knew very little about the problem or situation which the United States faces. I therefore made a study of all the facts concerned and came to the conclusion that private medical care has great advantages over the compulsory medicare plan. The reasons for my conclusion are summed up in this essay.

First, let us look at the magnitude and seriousness of the problem concerning our elderly persons.

Income of Elders Not Inadequate

The incomes of the aged, persons over 65, are inadequate for even a modest level of living. This has been said by advocates of federalized medicine. Let us look deeper into this and other statements which are deceptive in analyzing the economic and health conditions of the aged. For instance, the above statement was established by measuring the income of a mythical aged couple living in a hypothetical metropolitan city against the Labor Department's level of adequacy. However, the income figure used was not that of the elderly couples dwelling in metropolitan areas, but that of all elderly couples in the nation, including those in rural areas where the cost of living is substantially less. Excluded from this fictionalized situation are the U. S. Department of Labor figures which show that the income of the aged dwelling in metropolitan areas is significantly higher than the national median.

Fewer Obligations

Elderly couples have fewer family obligations, less debt, more homes mortgage free, and they enjoy special tax advantages. Between 1960 and 1961 the income of families headed by an older person rose more than twice as much as the increase of all families. A University of Michigan survey showed that 96% of all the aged did not owe any money to a doctor, dentist, or hospital. Also stated was the fact that of medicare expenditures of persons over 65 in 1961, 3.8 billion or nearly three-fourths of the total expenditures were paid from private sources.

Elders Not Universally Frail

Proponents of federalized medicine repeatedly portray our aged as universally frail, feeble and constantly ill. This is achieved by declaring that the elderly visit doctors 36% more than younger people, and that four-fifths of our aged has one or more chronic illness. These statistics are misleading because: the 36% visits can be translated to only 1.8 more visits per year, and "chronic illness includes non-disabling afflictions such as hay fever and varicose veins." Thus 84.5% of the aged either has no chronic condition or is without serious limitations of major activity.

In this summary of statistics I am trying to convey the opinion which I concluded,

Continued

that is, many of the aged can afford the health care they need without federal aid.

Undoubtedly there are many people who are not inclined to share my opinion on the economic and health conditions of the aged. The results are bills introduced providing medical care for the aged of which the most recent is the King-Anderson Bill. At this time a discussion of this bill is appropriate.

Many Not Covered

The proposed bill would provide limited health care benefits for everyone over 65 under the Social Security and Railroad Retirement Acts, and some 2,500,000 persons who are 65 and over not covered by the two acts. It would provide 45 days of hospital care free, or 90 to 180 days of nursing home service under certain conditions, diagnostic services above the first $20, and some other health services.

Drugs and Doctors Fee Not Covered

Now let's look at the other side of the picture, by pointing out some health care benefits which are not provided by the bill. It would pay practically no doctor bills. Any drugs or devices outside a hospital would not be furnished, as well as the cost of diagnosis as not part of a hospital service. It would provide no help for those confined in mental or tubercular hospitals. In other words, "it would cover less than one-quarter of the total yearly health care costs of the average aged person."

Cost Underestimated

Additional grounds of disapproval to the bill are its cost and its provision of a "free choice" in seeking health care. For the bill's first year in operation, the cost has been estimated at from $1.4 billion to $25 billion and England's socialized medicine program now costs nearly five times the original estimates. Also, the bill claims to give a free choice in medical care services, yet only participating hospitals, physicians on the staff of participating hospitals, and nursing homes affiliated with such a hospital are eligible to the program. Thus, personal physicians and preferred nursing homes might be disqualified. From these facts, I find not only the proposed bill unfavorable and inadequate for the health care of our aged, but also find its implications dangerous.

Questions may now arise in your mind, as they did in mine, concerning what provisions there are for health care of the aged in our contemporary society.

Health Insurance Available

First, can the aged get health insurance? The answer is yes. Today 450 insurance organizations now offer hundreds of policies available to all aged. They offer a wide range of choice in benefits and premium costs. More than 60% of the aged are now protected against the cost of illness through health insurance.

Second, are there any provisions today for the aged that need financial help? Yes, the Kerr-Mills Law was passed by Congress in 1960. This bill has two objectives, one, to improve and establish state health care programs for the needy, and two, establish new health care programs for the near-needy. Through this program, the federal and individual state governments work together to guarantee every aged American the health care he needs. The Kerr-Mills Law has many advantages over the proposed Medicare Bill. It permits individual states to develop and change their programs as experience shows changes to be desirable. Free choice of hospitals and doctors is mandatory under state programs. This program helps only those who need help, thus avoiding waste of tax dollars.

Reports prove that the Kerr-Mills program has been a successful program. "Thousands of needy and near-needy older persons across the nation are receiving medical, hospital and nursing home care every day under Kerr-Mills program." Furthermore, over 93% of 17.5 million aged live in states which adopted the Kerr-Mills program. The few states not adopting this program feel that existing state and local programs are taking care of their needs.

The conclusion I have drawn is that there are adequate provisions for the health care of the aged under private insurance organizations and existing programmed financial aid.

Principle of Subsidiarity

I feel an important question in the controversy over Medicare is, whether federalized medical care complies with the ideals set forth in the Principle of Subsidiarity. The Principle of Subsidiarity, as I have interpreted it, is the standard for deciding which functions the government should assume and which it should leave to individuals and lesser groups. This principle steers a course between two extremes, Individualism, through which the government is limited to the negative function of maintaining order, and Collectivism, through which all social functions are given over to the state. According to the Principle of Subsidiarity, it is wrong to hand over to the government that which individuals or individual groups can accomplish through initiative and enterprise. In the arguments which I have brought forth, I have tried to show that individual groups can accomplish the duty of providing health care for the aged. Therefore, I find it dangerous to transfer this duty to the Federal government.

Professional Freedom Endangered

From the point of view of the medical profession, professional freedom is an important part of the American way of life. This freedom has given the American Medical Profession the high position of respect that it holds in the world today. Its contribution to medical science has caused the countries of the world to look to America for the alleviation of their medical problems. Although the Medicare Bill won't provide complete absence of professional freedom, many fear that this bill will lead to that. Federalized medicine, I feel, would endanger the quality of our medical care. I do not stand alone in this evaluation in that the American Medical Association and doctors openly convey the same opinion in quotes such as, "I sincerely believe that the free practice of medicine, which has given our people the best medical care in the world, is in jeopardy."

Loss of Individuality

Three conditions are brought about when the government finances and operates medical services to some extent. *First,* the relationship between the patient and the doctor is not wholly voluntary. Therefore, the patient won't have full confidence in the doctor and the doctor won't have his heart fully in his work. *Second,* when the doctor is paid by the Government and not by the patient, he comes to work for the Government and not the patient, thus degrading the quality of medicine. *Third,* incentive is lost, and it is essential for good medical practice that there be maximum incentives for the doctor to do his best work and constantly improve himself.

Inadequate Supply of Student Doctors

Greater federal activity in health care would cause many medical students to abandon their study and others to leave the United States upon graduation. It's a known fact that we have a shortage of good doctors in our country today, therefore, not only the quality, but also the quantity of health care could decrease. Professional freedom is essential for an adequate supply of physicians and a high quality of medicine.

Conclusion

Through these facts and arguments which I have presented I have attempted to support the stand I hold on the Medicare issue. From this research I draw the conclusion that private medical care is highly advantageous for the following: the taxpayer . . . costs of taxes won't soar; the aged . . . free choice in medical care; doctors . . . freedom of profession and quality medicine; our governmental system . . . private enterprise will remain to thrive; and my future . . . a free society surviving and flourishing.

Diabetes Week, November 14-20

Paleopathology III: Egypt*

What diseases ancient Egyptians endured are partially recorded in mummies which underwent roentgenographic examination by Roy Moodie in his capacity as Paleopathologist for the Wellcome Historical Museum in London, the results of which were published in the Anthropology Memoirs of the Field Museum of Natural History, which in 1926 established a Division of Roentgenology to study ancient morbidities and disabilities.

In examining the mummies at the Field Museum special care had to be exerted to distinguish between actual body bone and tissue on the one hand, and extraneous materials on the other: sand and other detritus intruded by time and nature, as well as burial artifacts inserted by survivors. Furthermore, the mummy remains were sometimes so altered by embalming substances and so mutilated by vandals as to obscure and distort the pictures from which the data were to be derived.

Found to be prevalent, however, were numerous familiar pathologies such as arthridites, fractures with and without callus, and arteriosclerosis — occurring, curiously, among both young and old alike, and due to no known dietary cause. Also in Egyptian mummies paleopathologists have found evidences of pneumonia, smallpox, necroses, tumors, alveolar osteitis, and cirrhosis of the liver.

That these early people suffered from renal disease is apparent from traces of abscesses and of calcified bilharzia eggs in their kidneys. Schistosomiasis was not uncommon. Hypertrophied spleens demonstrate damage from malaria. A case of hydrocephalus was observed — with partial paralysis on one side. The mummy of one young adult presented evidence of a psoas abscess associated with either Pott's disease or tuberculosis. In the catacombs at Alexandria another mummy revealed a pelvic osteosarcoma.

Apparently spondylitis deformans was not rare among ancient Egyptians; Nefermaat of the Third Dynasty (2980-2900 B.C.) exhibited a solid bone block from the fourth cervical vertebra to the coccyx. Some mummies show Bouchard's nodosities, an indication of gastrectasis. Osteoporosis of the skull resulting in patches of porous bone was also common — due doubtless to some unidentified nutritional disturbance.

Paleopathologist Marc Ruffer made a special study of the mouth and teeth in ancient Egyptian mummies and found impaction, attrition, caries, abscesses and fistulae, periodontitis, and particularly absorptive osteitis due to pyorrhea: that ubiquitous and perennial scourge present on the evolutionary ladder from fossil animal right up to modern man.

Specific search was made by Mr. Moodie for evidence of calculi in the Egyptian mummies under scrutiny, but none was found in the kidneys, gallbladders, or urinary bladders of the individuals he examined and reported on. Roentgen rays, however, fail to reveal all of the lesions possibly present in wrapped mummies, such as trepannings, club injuries, slingshot wounds, and linear fractures, these being apparent only on more direct examination of the remains.

On the basis of 15 Egyptian mummies studied the incidence of disease was estimated at 40 per cent. However, a study based on larger numbers might well show a lower incidence. Nevertheless, the figures available are significant and challenging in the long-range perspective on man and his diseases.

MEETINGS AND ANNOUNCEMENTS

NOVEMBER

Inaugural Scientific Program of the new Ancker Hospital, St. Paul, will be held November 11-13. Program will include two days of general medical meetings. Contact: James F. Hammarsten, M.D., Ancker Hospital, St. Paul.

Wisconsin Society of Pathologists Meeting, November 13-15, Pathology Department, Marquette University, School of Medicine, Milwaukee. Contact: Joseph L. Teresi, M.D. at 561 North 15th St., Milwaukee.

ANNOUNCEMENTS

Hahnemann Medical College & Hospital, Philadelphia, postgraduate courses:

Nov. 22-24 — Symposium Cancer Chemotherapy, Sheraton Hotel.

* * *

A nine month tutorial program in Cardiology, September 15, 1965 to June 15, 1966, will be offered by Institute for Cardio-Pulmonary Diseases, Scripps Clinic and Research Foundation, La Jolla, California. For details: Write E. Grey Diamond, M.D., Scripps Clinic and Research Foundation, La Jolla, California.

* * *

The University of Minnesota Department of Pediatrics continuation course in pediatrics, September 21-23, University of Minnesota Campus in Minneapolis. "Genesis, Epigenesis, Modern Physic and the Child" is the subject. Contact: Edward Defoe, M.D., Department of Pediatrics, University of Minnesota Hospitals, Minneapolis 55455.

* * *

Three day meeting in Cardiology at the Lowry Hotel, St. Paul, September 15-17, under the sponsorship of the Council on Clinical Cardiology of the American Heart Association, the St. Paul Medical Center, and the Minnesota Heart Association.

The focus of this three-day postgraduate course will be on functional pathology of valvular and pericardial diseases — congenital and acquired types.

The course will be directed by Jesse E. Edwards, M.D., Director of Laboratories at Charles T. Miller Hospital and board member of the American Heart Association. Doctors Lewis S. Carey, Robert S. Eliot, James N. Karnegis and James Ronan will be on the faculty.

Happiness is that peculiar sensation you acquire when you are too busy to be miserable.

— Mutual Moments

People are usually willing to meet each other half way, but their judgments of distances vary considerably. — The Rodney (Ont.) Mercury

Indications: Many types of edema involving retention of salt and water.
Contraindications: Hypersensitivity and most cases of severe renal or hepatic disease.
Precautions: Reduce dosage of concomitant antihypertensive agents by at least one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take special care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.
Side Effects: Agranulocytosis, constipation, dizziness, dysuria, headache, hyperglycemia, hyperuricemia, impotence, leukopenia, muscle cramps, nausea, postural hypotension, purpura, thrombocytopenia, transient myopia, urticaria, vomiting and weakness.
Average Dosage: One tablet (100 mg.) daily with breakfast.
Availability: Tablets of 100 mg. in bottles of 100 and 1000.
For full details, see the complete prescribing information.

WANTED PEDIATRICIANS AND INTERNISTS. Office space now available in new, modern, well established center — excellent opportunity for good earnings and professional pursuits — fastest growing suburban area. Write or phone A. G. Erickson, 7033 Edgewood Avenue North, Minneapolis Tel 533-7332.

WANTED: Board Certified or eligible internist to associate with group in large, active practice in Minneapolis. Group consists of Surgeon, Obstetrician, Pediatrician and Internist maintaining downtown and suburban offices. Partnership in mind. Contact: Jesse J. Barron, M.D., 1127 Medical Arts Building, Minneapolis, Minnesota 55402, FEderal 2-8259."

FOR RENT: Successful medical building. Opportunity for doctor to start new group. Rent at less than $3.00 square foot. Deluxe, modern, air-conditioned, all brick building with capacity up to four doctors. Located at 36th Avenue North and Noble Avenue in Northwest Suburban Minneapolis. For further information: Call Noble Drug at 588-9449 and ask for Ben or Lou.

MORGAN, MINNESOTA, Wants General Practitioner — present physician retiring after 33 years. Opportunity to take over well established practice. Progressive community in the best rural area of Southern Minnesota. Office space and equipment available. Call or write John Hageman, Pharmacist, Morgan, Minnesota. Telephone Morgan No. 96.

WHITE BEAR LAKE, MINNESOTA. A suburban community of 35,000 and growing fast. Available several ground floor air-conditioned suites in fireproof building in central business district, free municipal parking lot at second entrance in rear. See: N. R. Dittberner, 316 Washington Avenue, White Bear Lake. Telephone: Collect anytime 429-7787.

BUSY, GROWING aggressive 3-man partnership in Northwest Wisconsin serving a trade area of 15,000 needs a well-trained recent graduate with fulfilled military obligations to associate immediately on excellent salary, with partnership in 1 year if mutually agreeable. Modern 15 room air conditioned brick clinic building is being doubled in size this year. 32 bed hospital and new 42 bed nursing home one minute from clinic. New 1500 student consolidated school. Excellent hunting, fishing and outdoor sport facilities in immediate area. Contact: MINNESOTA MEDICINE — 317; 496 Lowry Medical Arts Building, St. Paul 55102.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with early partnership. Write: MINNESOTA MEDICINE — 289; 496 Lowry Medical Arts Building; St. Paul, 55102.

WANTED: Generalist to associate with two man partnership in Northern Minnesota. Community has a thirty seven bed hospital, X ray and laboratory technicians and nurse anesthetist. Good hunting and fishing. Adequate salary and time off. Contact: A. G. Janecky, M.D., Baudette Clinic, Baudette, Minnesota.

PROFESSIONAL AIR AMBULANCE. Multi or single engine aircraft. All weather and night flight capability, anywhere in the U. S. Oxygen, Respirator, Aspirator, Nursing service, all medications. Also full time M.D. Board Anesthesiologist providing all medical care in flight available on request. MIDWEST AIR TRANSPORTS, Operations Office, Municipal Airport, Waterloo, Iowa, Phone 319-2331083.

A 13 MEMBER specialty group in the Midwest will need several men to replace and add to present staff. This has been a rewarding group for years, is now, and will be for years to come. We need 3 internists, 1 dermatologist, 1 ob-gyn, 1 pediatrician, 1 general and thoracic surgeon, 1 orthopedist, 1 ophthalmologist, 1 otorhinolaryngologist, and 1 psychiatrist. This is a very good town for a family man. Three colleges (1 a State College). Good schools and excellent recreation programs. Good hunting, fishing and water sports. Applicants should be Board certified or completing requirements. Write MINNESOTA MEDICINE — 324; 406 Lowry Medical Arts Building, St. Paul 55102.

EASTERN ST. PAUL, FOR RENT — spacious suite in new building for 1, 2 or group of physicians. Ideal second office. Adjacent to busy shopping center. This rapidly growing area has need for physicians. Henry Oselka, D.D.S., 1618½ White Bear Ave., St. Paul, 774-7144.

OFFICE SPACE now available in busy Bloomington. 713 square feet of new space in building with busy group of G.P.'s, dentist and suburban OB-GYN office. Ideal for ophthalmology, ENT or pediatrics. 8040 Penn Avenue South. 888-9211.

GENERAL PRACTITIONER WANTED by three local physicians and community. Population 3500. New 45 bed municipal hospital. Contact: Rex Beech, Sleepy Eye, Minnesota, Phone 794-5111.

WANTED GENERAL PRACTITIONER OR SURGEON space available July 15th for party interested in a very active solo professional pursuit. Ideal air conditioned suite, an opportunity that must be seen. Contact A. G. Erickson, 7033 Edgewood Avenue North, Minneapolis, or phone 533-7332.

PART TIME INTERNIST OR GENERAL PRACTITIONER. Good compensation — Midway Area. Alfred F. Anderegg, M.D.; 2500 Como Avenue, St. Paul, Minnesota.

OPENING AVAILABLE — approved. First year surgical residency for physician planning on entering Residency Program in Surgical Specialties. For complete details write: Director of Medical Education, Saint Joseph's Hospital, 69 West Exchange Street, St. Paul, Minnesota 55102.

PSYCHIATRIC RESIDENCIES: Positions available July 1966. Fully approved; balanced didactic and clinical experiences. Five-year career program: $8,895, $10,294, $12,048, $15,368, $16,203; NIMH General Practitioner Stipends $12,000 annually for three years. In Michigan's Water-Winter Wonderland. Contact: Dr. M. Duane Sommerness, Medical Superintendent, Traverse City State Hospital, Traverse City, Michigan. An equal opportunity employer.

WANTED INTERNIST, Board qualified or certified for 22-physician mixed group of general practitioners and specialists (East Range Clinic, Virginia, Minnesota). Salary first year, then full partnership. Centrally located in area of rapidly expanding economy.

WANTED: one or two general practitioners. Excellent clinic and hospital facilities. Rural practice established 18 years. Salary open, partnership if compatible. Lloyd H. Klefstad, M.D., Greenbush, Minnesota.

GENERAL PRACTITIONER: well established multi-group specialty fourteen man group (seven GP's) Mid-western city, population 30,000; beginning salary then partnership; no investment; clinic building six years old; excellent school, hospital and recreational facilities. Write: MINNESOTA MEDICINE — 307, 496 Lowry Medical Arts Building, St. Paul 55102.

G.P. FULLY EQUIPPED office in new building with X-ray, P.T. and full lab facilities. Present man leaving for Florida in November. Practice grosses $75,000 a year. No outlay of cash. Terms agreeable. Introduction period by moving physician. Move fast to get this dandy. A. H. Wolf, M.D., 3145 Hennepin Avenue, Minneapolis 55408.

SACRED HEART, MINNESOTA, doctorless since 1961, wants general practitioner. Population 700, accredited hospital 10 miles away. Write: Rev. Robert Bardy, Phone 765-2547, Sacred Heart, Minnesota.

INTERNIST: seven-man group desires services of another Board eligible internist. Located Central Minnesota. Approved 125 bed hospital. Excellent public and parochial schools. Junior state college. Close to State University and many private colleges. Marvelous fishing, hunting and golf facilities. Supervised youth activities. Salary negotiable. Full partnership available in eighteen months. Many fringe benefits. Write: MINNESOTA MEDICINE — 321; 496 Lowry Medical Arts Building, St. Paul 55102.

GENERAL PRACTITIONER FOR PERMANENT POSITION — salary open, under thirty-five years of age, partnership agreement negotiated in 18 months, scheduled post graduate and vacation periods. New modern medical-dental clinic with full diagnostic facilities at High 100 and Wayzata Blvd. Large established family practice with opportunity for surgical privileges. Contact: Alton C. Olson, M.D.; 5250 Wayzata Blvd., Minneapolis, Telephone 545-1661.

GENERAL PRACTITIONER WANTED to be associated with 40-year old general practitioner. Winona, Minnesota. Excellent practice conditions. 3.5 million dollar hospital. Write: MINNESOTA MEDICINE — 322; 496 Lowry Medical Arts Building, St. Paul 55102.

GENERAL MEDICAL AND SURGICAL PRACTICE Metropolitan Area. Gross $90 M. Modern 14 room clinic. Liberal terms with low-down payment. Leaving to enter residency. Write: MINNESOTA MEDICINE — 323; 496 Lowry Medical Arts Building, St. Paul 55102.

FOR SALE: general practice, over $50,000 gross, county seat, 40 bed hospital. South Central Minnesota. Equipment for sale, office for lease. Leaving for residency. Write: MINNESOTA MEDICINE — 318; 496 Lowry Medical Arts Building, St. Paul 55102.

On Bloodletting

A medical manuscript of the twelfth century expounds on the virtues of bloodletting:

It contains the beginning of health, it makes the mind sincere, it aids the memory, it purges the brain, it reforms the bladder, it warms the marrow, it opens the hearing, it checks tears, it removes nausea, it benefits the stomach, it invites digestion, it evokes the voice, it builds up the sense, it moves the bowels, it enriches sleep, it removes anxiety, it nourishes good health . . .*

The author is anonymous.

GERIATRIC SYNDROME

when a change in environment overwhelms him with anxiety

Failing health, financial difficulties, or the death of a spouse are among the reasons why elderly people may be obliged to leave their familiar surroundings. Moving in with children or entering a home for the aged may satisfy practical requirements but can be psychologically traumatic since emotional resilience tends to diminish with age.

Even when anxiety reaches overwhelming proportions, you can counteract it promptly with the potent tranquilizer—Atarax (hydroxyzine HCl).

The outstanding systemic safety record of Atarax makes it particularly suitable for geriatric patients whose drug tolerance is often low. The usual initial dosage in such patients is 50 mg. q.i.d. However, this tranquilizer is so well tolerated that dosage can be adjusted to meet individual requirements. The wide variety of dosage forms allows flexibility of administration from any standpoint—convenience, patient preference, or emergency requirements.

No age, of course, is exempt from anxiety and any number of circumstances can unleash it. Keep Atarax in mind for *all* your emotionally distressed patients—from under 6 to over 60.

for any age—for any stage of anxiety

Rx **ATARAX**®

(hydroxyzine HCl) tablets syrup parenteral

...In any condition where tissue depletion of the water-soluble vitamins is found, Rx **RoeriBeC**® therapeutic B complex with 500 mg. of vitamin C.

J. B. Roerig and Company
Division, Chas. Pfizer & Co., Inc.
Science for the World's Well-Being®
New York, New York 10017

Side effects and precautions: The transitory drowsiness which may occur with hydroxyzine HCl usually disappears spontaneously in a few days with continued therapy, or is correctable by dosage reduction. Dryness of the mouth may be seen with higher doses. Involuntary motor activity has been reported in hospitalized patients on higher than recommended doses. Hydroxyzine HCl may potentiate CNS depressants, narcotics such as meperidine, barbiturates, and anticoagulants. In conjunctive use, dosage for these drugs should be decreased. Because drowsiness may occur, patients should be cautioned against driving a car or operating dangerous machinery. **Parenteral Solution Precautions and contraindications:** This dosage form is intended only for I.M. or I.V. administration and should not, under any circumstances, be injected subcutaneously or intra-arterially. When the usual precautions for I.M. injection have been followed, reports of soft tissue reactions have been rare. I.V. administration should be slow, no faster than 25 mg. per minute, and should not exceed 100 mg. in any single dose. Particular care should be used to insure injection only into intact veins; a few instances of digital gangrene occurring distal to the injection site have been attributed to inadvertent intraarterial injection or periarterial extravasation, both of which should be avoided. **More detailed professional information available on request.**

nicotron™ Nicotinic Acid and Aminoacetic Acid (Glycine)

Like Radiant Sun

Warms Cold Hands and Feet

nicotron™
NICOTINIC ACID +
AMINOACETIC ACID (Glycine)

increases and sustains peripheral blood flow **(1-2)**

INDICATIONS: Poor circulation causing cold hands and feet or pain on walking. For the more serious peripheral vascular disturbances such as . . . Raynaud's Disease, Meniere's Syndrome, intermittent claudication, diabetes, post-phlebitis syndrome, leg ulcers due to venostasis and chronic thrombophlebitis.

DOSAGE: 1 or 2 teaspoonfuls or 1 or 2 tablets 3 times a day before meals. The feeling of warmth and tingling of the skin is a desirable effect. If this reaction is too pronounced reduce dosage.

CONTRAINDICATIONS: There are no known contraindications.

SUPPLIED: 8 oz. bottles and bottles of 100 chew-tabs.

FORMULA: Each teaspoonful (5ml.) elixir or each chew-tab contains:
Nicotinic Acid . . . . 75 mg.
Aminoacetic Acid (Glycine) . . . 750 mg.

When uncontrolled diarrhea brings a call for help

When the diarrhea sufferer has run the gamut of home remedies without success, pleasant-tasting CREMOMYCIN can answer the call for help. It can be counted on to consolidate fluid stools, soothe intestinal inflammation, inhibit enteric pathogens, and detoxify putrefactive materials—usually within a few hours.

CREMOMYCIN combines the bacteriostatic agents, succinylsulfathiazole and neomycin, with the adsorbent and protective demulcents, kaolin and pectin, for comprehensive control of diarrhea.

Indications: Diarrhea. *Contraindications:* Kaolin: Withhold if diverticulosis is present or suspected. *Precautions:* Sulfonamide: Continued use requires supplementary administration of thiamine and vita-

your ℞ for Cremomycin can provide relief

min K. Neomycin: Patient should be observed for new infections due to bacteria or fungi. *Side Effects:* Sulfonamide: Sensitivity reactions may occur (e.g., skin rashes, anemia, polyneuritis, fever; agranulocytosis with a fatal outcome has been reported). Reduction of thiamine output in the feces and of vitamin K synthesis has been observed. Neomycin: Nausea, loose stools possible.

Before prescribing or administering, read product circular with package or available on request.

promptly relieves diarrheal distress

with
REASSURING SAFETY FACTORS

Effectiveness, dependability and reassuring Safety Factors make PABALATE-SF a logical choice for antiarthritic therapy in elderly patients—even when osteoporosis, hypertension, edema, peptic ulcer, cardiac damage, latent chronic infection and other common geriatric conditions are present. The potassium salts of PABALATE-SF cannot contribute to sodium retention...the enteric coating assures gastric tolerance...and clinical experience shows that this preparation does not precipitate the serious reactions often associated with corticosteroids or pyrazolone derivatives.

Side Effects: Occasionally, mild salicylism may occur, but it responds readily to adjustment of dosage. Precaution: In the presence of severe renal impairment, care should be taken to avoid accumulation of salicylate and PABA. Contraindicated: An hypersensitivity to any component.

Also available: PABALATE—when sodium salts are permissible. PABALATE-HC—Pabalate-SF with hydrocortisone.

Physician's Diary

Good company and good discourse are the very sinews of virtue. — Isaak Walton

The 75th Anniversary seal of the College of Medical Sciences, University of Minnesota, depicts the tree of life, one of the earliest medical symbols in ancient Eastern cultures. The pine cone, fruit of the tree of life, was believed to have both healing and supernatural powers.

* * *

Dr. Everett J. Schmitz was elected chief of the St. Cloud Hospital medical staff at the annual meeting of the group. Other officers elected were: **Dr. E. M. LaFond**, vice-chief of staff and **Dr. A. T. Rozycki**, secretary.

* * *

Dr. Randall G. Sprague, senior consultant in medicine in the Mayo Clinic, Rochester, was given the Banting Memorial Award of the American Diabetes Association for his original clinical investigations in metabolic diseases.

* * *

Dr. George C. Flora, assistant professor, psychiatry-neurology, and **Jack W. Miller**, associate professor, pharmacology, were the winners of the 1965 Minnesota State Medical Association's Distinguished Teaching Awards. Presentation was made by **Dr. J. Minott Stickney** of Rochester, President of the Association, during the annual medical awards day program at the University of Minnesota. The 1965 senior medical class graduates in the 75th anniversary year celebration of the establishment of the University of Minnesota Medical School with 148 members, the largest ever to graduate.

* * *

Dr. Laurentius O. Underdahl, head of a section of medicine in the Mayo Clinic, was elected president of the American Diabetes Association at its annual meeting in New York City, and **Dr. C. Allen Good**, head of the section of diagnostic roentgenology of the Mayo Clinic, was elected president of the American Board of Radiology, Inc. at its meeting of the board at San Francisco.

* * *

After twenty-nine years as obstetrician and gynecologist with the Worthington Clinic, **Dr. F. L. Schade**, has retired. It is believed that Dr. Schade has delivered more than 5,000 babies in Worthington. **Dr. and Mrs. Schade** plan to leave Worthington for ranch life near Santa Cruz, California.

Dr. William C. Bernstein, clinical professor of surgery at the University of Minnesota, was elected vice-president of the American Proctologic Society at its annual meeting.

* * *

NEW LOCATIONS: **Dr. Charles W. Quimby, Jr.** has joined the medical staff of the Community Memorial Hospital in Winona . . . **Dr. Roy Daumann** of Madison will join the Jackson Medical Center . . . **Dr. Robert Mathisen** of Fridley will practice in Annandale . . . **Dr. Darrel W. Siebert** opened up an office in Pipestone . . . **Dr. Arnold Overland** will leave the Klefstad Clinic in Greenbush to practice in Rolla, North Dakota . . . **Dr. James Schuft** is to leave Morris to specialize in radiology at the Charles T. Miller Hospital in St. Paul . . . **Dr. Arnold M. Berg** will leave Roseau to become an associate with the Falls Starekow Clinic in Thief River Falls . . . **Dr. Andrew N. Stiner** will begin practicing medicine in the Thielen Clinic in St. Michael . . . **Doctors Robert Conley, B. R. Geurs** and **A. M. Scheidel** have moved into new quarters in Mankato . . . **Dr. Bennie Faul** and **Dr. Bruce W. Wells** have joined the Worthington Clinic.

* * *

Dr. James R. Pluth, a fellow in surgery at the Mayo Clinic, received a surgical travel award for high achievement in surgery from the Mayo Graduate School.

* * *

Dr. E. A. Olson of Pine Island was recently honored for forty-one years of community service by that town. There was a parade, and a bronze plaque was presented to **Dr. Olson.**

* * *

Dr. James Nixon, Deerwood, has been appointed to serve as Crow Wing county coroner. Dr. Nixon, who is affiliated with the Cuyuna Range Clinic, will succeed **Dr. Maurice Meller.**

* * *

Dr. William H. Remine of the Mayo Clinic, was elected to president of the Minnesota Surgical Society at its meeting this month. **Dr. Harry Neel** of Albert Lea was named president-elect. **Dr. Jacob Strickler** of Minneapolis was chosen vice president and **Dr. Martin Adson** of Rochester was re-elected secretary-treasurer.

Minnesota Medicine at a Glance

Giant Russell Bodies, Schleicher Page 1125

Giant Russell bodies in neoplastic lymphoid cells have been reported but not extensively observed. This manuscript, with illustrations on the cover, is a masterful study and an excellent illustration of the giant Russell bodies in color.

A Cause of Gastrointestinal Hemorrhage, Myhre Page 1131

Though the usual cause of intestinal hemorrhage becomes readily evident, thrombocythemia has not been included in the list of causes for this gastrointestinal complication. It is well to keep in mind thrombocythemia as one of the possible causes of obscure hemorrhage, as detailed in this case report, and in a review of the literature.

Mediastinoscopy, Duvall & Koop Page 1135

Though there may be other methods of visualizing the mediastinum for masses, mediastinoscopy adds another method to the armamentarium of the surgeon who is desirous of making a full evaluation of the pathologic findings before making extensive surgical explorations.

Radioactive Isotope Scintiscanning, Loken Page 1138

Scintiscanning with the various types of isotopes opens a new field of exploration for visualization of many of the organs of the body. Visualization with a Geiger counter and the scanning produced is beautifully illustrated.

Tracheoesophageal Fistula, Calin and Mork Page 1144

The more common tracheoesophageal fistula seen in infants offers no problem, but the H-type fistula without atresia may be difficult to identify roentgenologically. When the clinical symptoms suggest, nevertheless, that a tracheoesophageal fistula does exist, cinefluorography with an exposure of 30 frames per second can be very valuable in establishing a diagnosis, thereby aiding the surgeon to do a definitive procedure which might otherwise be overlooked.

Neuropsychiatrist in a Court of Justice, Jeub Page 1147

This manuscript and the editorial on page 1155 are worth reviewing from the viewpoint of the neuropsychiatrist and that of the judiciary.

Dermatomyositis, Grand Rounds Page 1191

Dermatomyositis, a disease with a very grave prognosis, fortunately is not frequently seen, but when it is observed the outlook is universally fatal.

It begins insidiously with a variety of cutaneous manifestations, low grade fever, malaise, and minimal aches and pains in the extremities. In patients with atypical rheumatoid symptoms the disease should be suspected. The determination of an increase in the transaminase provides a valuable clue as to the continued progression of muscular necrosis which is evident in this disease. The use of steroids to suppress the inflammatory reaction of the muscle has been found to be of some clinical value, though the eventual prognosis continues to remain grave.

Antidepressant Drugs, Janecek Page 1197

Drugs for depressive symptoms are used in a variety of syndromes. There may be the grief-reaction syndrome, the endogenous syndrome in which the individual has a dismal, hopeless outlook and is severely impaired in self esteem; the repressed-rage syndrome; the pseudoneurotic schizophrenic syndrome, and lastly the maladjusted personality pattern.

The choice of drugs for these various syndromes is of significance, and it would be well to review this manuscript in order to have in mind general precautions to be observed in prescribing these drugs, as they may be inadvertently given to patients for whom they are not indicated.

Surgical Horizon, Wangensteen Page 1219

For a literary sketch of a surgical lifetime and a philosophy that has been engendered, the reading of this manuscript is well worth the half hour of pleasant reminiscences, into the history of medicine, which will be required to digest it.

BSP® DISPOSABLE UNIT

H.W.&D. BRAND OF SULFOBROMOPHTHALEIN SODIUM INJECTION, U.S.P.

(50 mg. per ml.)

Bromsulphalein (BSP), one of the most sensitive diagnostic agents for evaluating liver function, is now available in a new Disposable Unit. Each "unit" contains: A sterile BSP syringe calibrated in milliliters and pounds (utilizing the 5 mg./kg. BSP dosage schedule), a sterile disposable needle, alcohol swab and a 7.5 or 10 ml. size ampule of BSP.

The precalibrated dosage schedule imprinted on the syringe barrel makes weight calculations unnecessary—saving time and assuring proper administration of the dye, regardless of patient-weight.

Literature on indications and dosage available on request.

The NEW BSP DISPOSABLE UNIT is supplied in 7.5 and 10 ml. sizes in boxes of 10's and 25's.

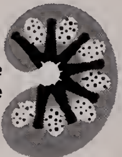
without side effects with NegGram, a specific urinary antibacterial.

NegGram clears most gram-negative urinary tract infections with a minimum of side effects: No fungal overgrowth • no crystalluria • no ototoxicity • no nephrotoxicity • no significant hematologic or hepatic disturbances. NegGram is so well tolerated that it can even be given to patients who suffer from moderate renal impairment. **Gram-negative urinary infection—cystitis, pyelitis, pyelonephritis, prostatitis, urethritis? Start first with NegGram..."a good 'starting' drug."**[1] NegGram "...treatment may be first choice in potentially curable gram negative bacterial urinary infections."[2]

*of a total of 1049 patients treated (Cooperative Study, Department of Medical Research, Winthrop Lab.)

treat the source
with optimal dosage



NegGram®
Brand of
nalidixic acid

Indications: Urinary tract infections caused by gram-negative and some gram-positive organisms.

Side effects: Mainly mild, transient gastrointestinal disturbances; in occasional instances, drowsiness, fatigue, pruritus, rash, urticaria, mild eosinophilia, reversible subjective visual disturbances (overbrightness of lights, change in visual color perception, difficulty in focusing, decrease in visual acuity and double vision), and reversible photosensitivity reactions. Marked overdosage, coupled with certain predisposing factors, has produced brief convulsions in a few patients.

Precautions: As with all new drugs, blood and liver function tests are advisable during prolonged treatment. **Pending further experience, like most chemotherapeutic agents, this drug should not be given in the first trimester of pregnancy. It must be used cautiously in patients with liver disease or severe impairment of kidney function.** Because photosensitivity reactions have occurred in a small number of cases, patients should be cautioned to avoid unnecessary exposure to direct sunlight while receiving NegGram, and if a reaction occurs, therapy should be discontinued. The dosage recommended for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Bacterial resistance may develop.

When testing the urine for glucose in patients receiving NegGram, Clinistix® Reagent Strips or Tes-Tape® should be used since other reagents give a false-positive reaction.

Dosage: Adults: Four Gm. daily by mouth (2 Caplets® of 500 mg. four times daily) for one to two weeks. Thereafter, if prolonged treatment is indicated, the dosage may be reduced to two Gm. daily. Children may be given approximately 25 *mg. per pound* of body weight per day, administered in divided doses. The dosage recommended above for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Until further experience is gained, infants under 1 month should not be treated with the drug.

How supplied: Buff-colored, scored Caplets® of **500 mg. for adults,** conveniently available in bottles of 56 (sufficient for one full week of therapy) and in bottles of 1,000. **250 mg. for children,** available in bottles of 56 and 1,000.

GENERAL INFORMATION

Authors

Manuscripts for consideration in Minnesota Medicine should be addressed to Office of Publication, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102. Papers should be typed double spaced on white paper with a wide margin. The first page should list the title, the name of the author (or authors), degree, and any institutional or other credits. Pages should be numbered consecutively. Tables should be typed and numbered and should have a brief descriptive caption.

Bibliographical references should be limited to twelve and should be typed in conformity to the method used by the Index Medicus. They should be numbered consecutively in the order in which they first appear in the text. Book references should give the name of the author, title, edition number, publisher, and the year.

Illustrations (photographs, tables, and graphs) should be submitted on separate sheets of paper and not combined in the text. Instructions for combining photographs are acceptable.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Anatomy of
Low Back Pain #1
the sedentary life
is often the seat of
low back pain

The human spine is not engineered f
prolonged sitting at desks, pianos, typ
writers and drafting boards. The stress
set up by the heavy, forward-tilted he
and trunk, balanced precariously on
insufficient base, result in strain of t
dorsal musculature, particularly at t
low lumbar level.

The unusual muscle-relaxant and an
gesic properties of 'Soma' make it esp
cially useful in the treatment of low ba
sprains and strains. 'Soma' is wide
prescribed ☐ **to relieve pain** ☐ **to rel**
muscles ☐ **to restore mobility.**

Indications: 'Soma' is useful for management
muscle spasm, pain, and stiffness in a variety
inflammatory, traumatic, and degenerative musc
loskeletal conditions. It also may act to normali
motor activity in certain neurologic disturbanc

Contraindications: Allergic or idiosyncratic re
tions to carisoprodol.

Precautions: 'Soma', like other central nervo
system depressants, should be used with cauti
in patients with known propensity for taking
cessive quantities of drugs and in patients wi
known sensitivity to compounds of similar che
cal structure, e.g., meprobamate.

Side Effects: The only side effect reported with a
frequency is sleepiness, usually on higher th
recommended doses. An occasional patient m
not tolerate carisoprodol because of an individ
reaction, such as a sensation of weakness. Oth
rarely observed reactions have included dizzine
ataxia, tremor, agitation, irritability, headache,
crease in eosinophil count, flushing of face, a
gastrointestinal symptoms.

One instance each of pancytopenia and leu
penia, occurring when carisoprodol was adm
istered with other drugs, has been reported, as
an instance of fixed drug eruption with carisopro
and subsequent cross reaction to meprobama
Rare allergic reactions, usually mild, have includ
one case each of anaphylactoid reaction with m
shock and angioneurotic edema with respirat
difficulty, both reversed with appropriate thera
In cases of allergic or hypersensitivity reactio
carisoprodol should be discontinued and approp
ate therapy initiated. Suicidal attempts may p
duce coma and/or mild shock and respirat
depression.

Dosage: Usual adult dose is one 350 mg. tab
three times daily and at bedtime.

Supplied: Two Strengths: 350 mg. white tabl
and 250 mg. orange, two-piece capsules.

Before prescribing, consult package circular.

President's Letter

This is the time of year when we get back into full activity. The doctor who is looking for an opportunity to serve his profession in the coming year has unlimited outlets for his interests. Many of them are more or less thrust upon him in his busy life. As the ratio of doctors to population has been decreasing, more and more controls have been established which influence the operation of a physician's practice of medicine. These controls have been created to assure quality medical care by such important groups as the Joint Commission on Hospital Accreditation, the State Department of Health, the City Board of Health, Public Assistance Agencies at the local, state and federal level, Blue Cross and Blue Shield and other carriers, the local hospital council, area-wide hospital planning groups, and medical schools where there is an affiliation. As though conformance with the wishes and regulations of these agencies is not enough, the doctor is expected to reciprocate for staff privileges through service in hospital, clinics or the emergency room, to attend rounds, medical staff meetings, and to be well read in the latest medical developments and to have at his fingertips all information about drug products. In addition, he is expected to participate in research projects and to serve in the hospital on committees such as those for medical records, tissue, and utilization. With all of this he is expected to be a civic leader in his community.

In the local medical society there are offices and committees to be filled. At the state level there are 24 scientific committees ranging alphabetically from The Committee on Aging to the Committee on Rheumatism, the first and last not necessarily being related. There are 21 non-scientific committees concerned with all phases of public relations. In a few weeks the Council and the President of the Minnesota State Medical Association will appoint the committees for the year 1966. It is this committee structure of the Association which I wish to discuss. In most instances the Council and the House of Delegates rely upon the committees for reference and investigation of pertinent subjects. In addition, the committees ought to be a source of thoughtful suggestions for the introduction of new policies and the revision of old ones. Their work is really the life-blood of the Association. The Council and the President, in appointing these committees, try to make them representative and effective by selecting men who have interest and competence in the relative fields. To promote a healthy organization it is desirable to bring in new members each year, while retaining those who have shown interest and ability. There is no better place for a young physician to get started in State Association work. Most of our present leaders have come up through the committees of the local societies and the Minnesota State Medical Association.

While the councilors and the state officers may know of most of those who can be considered for appointment, it is obvious that local initiative on the part of a county medical society or an individual in making candidates known is desirable. Secretaries of the

a significant price decline in the cost of V-Cillin K®

V-Cillin K now costs approximately 21 percent less. This significant price decline constitutes a substantial saving and still offers these important benefits over penicillin G:

The effectiveness of intramuscular penicillin. Just three 250-mg. doses daily provide total twenty-four-hour penicillin blood levels equal to those achieved by injection of 600,000 units of procaine penicillin G. A fourth dose increases daily penicillemia to levels 35 percent above those achieved by injection.

Consistent dependability—even in the presence of food. Comparative pharmacologic data show that V-Cillin K produces peak blood levels *twice* as high as those of penicillin G, with *half* the dose.

New, thin coating . . . new size and shape. The new coating eliminates the characteristically bitter taste of oral penicillin and makes V-Cillin K tablets easy to swallow. The new shape makes them easy for physicians and pharmacists to identify.

Indications: V-Cillin K is an antibiotic useful in the treatment of streptococcus, pneumococcus, and gonococcus infections and infections caused by sensitive strains of staphylococci.

Contraindications and Precautions: Although sensitivity reactions are much less common after oral than after parenteral administration, V-Cillin K should not be administered to patients with a history of allergy to penicillin. As with any antibiotic, observation for overgrowth of nonsusceptible organisms during treatment is important.

Usual Dosage Range: 125 mg. (200,000 units) three times a day to 250 mg. every four hours.

Supplied: Tablets V-Cillin K, 125 or 250 mg., and V-Cillin K, Pediatric, 125 mg. per 5-cc. teaspoonful, in 40, 80, and 150-cc.-size packages.

V-Cillin K®

Some Anatomical Features of the Heart Relative to Normal and Abnormal Function

GEORGE C. RINKER, Ph.D.*
Vermillion, South Dakota

THE HEART OCCUPIES the middle mediastinal region of the thoracic cavity. When the outline of the average heart is projected anteriorly onto the thoracic cage, its base is oriented across the sternum at the level of the third costosternal junction. The upper left margin of the left atrium is seen to present on the upper margin of the third rib at a point somewhat under an inch from the sternal margin (Fig. 1:1); while the junction of the superior vena cava with the right atrium projects on the lower margin of the right third rib about one half inch from the sternal margin (Fig. 1:2). The junction of the inferior vena cava with the atrium is seen to fall behind the chondrosternal junction of the sixth rib (Fig. 1:3). The apex of the heart lies posterior to the fifth intercostal space, just above the margin of the sixth rib, at a point approximately three and one half inches from the ventral midline (Fig. 1:4). The general outline of the heart can be obtained by connecting these points with suitable curved lines. The normal position of the valves of the heart and arterial trunks is also shown. It should be emphasized that the points given are averages and that any individual may show considerable variation from these. There is a rather predictable variation according to general body conformation. In short, broad persons the heart will tend to be more transversely disposed, while in a tall, thin individual it will usually be more vertically oriented. In a normal case, the heart will not occupy more than 50% of the transverse dimension of the thorax.

The base of the heart is relatively fixed by its continuity with the great vessels at the level of the bodies of the fifth to the ninth thoracic vertebra. From the roots of these vessels it hangs suspended in the pericardial sac, "resting" on the anterior slope of the dome of the diaphragm. Orientation of the heart is such that, as seen in the body, the anterior surface consists mainly of the right ventricle and atrium, with only a small area of the left ventricle and the tip of the left atrium visible from this view. The left atrium and ventricle make up most of the posterior aspect of the heart.

---

*Department of Anatomy, School of Medicine, University of South Dakota.

The fibrous base or "skeleton" of the heart consists of four dense fibrous rings surrounding the two atrioventricular orifices and the bases of the arterial trunks. These rings give attachment to the fascicles of the myocardium, completely separating the atrial musculature from that of the ventricles. Figure 2 shows schematically the relations of these rings to the major cardiac orifices. From the inner margin of each of the atrioventricular rings thin fibrous sheets extend downward into the ventricles. These, with their endocardial covering form the cusps of the atrioventricular valves (Fig. 2, 3). The fibrous rings supporting the bases of the aortic and pulmonary trunks give attachment to the semilunar valves which guard these exits. Relative positions and terminology of the valves of the heart are shown in Figure 2. For their sternocostal projections refer to Figure 1.

Blood Supply

Blood supply to the heart is derived from the two coronary arteries.

Right Coronary Artery

The right coronary artery arises from the right anterior aspect of the aorta, emerging from the right aortic sinus. It courses anteriorly, passing at first posterior to the pulmonary trunk, to reach the coronary sulcus in which it runs inferiorly, supplying branches to both the right atrium and ventricle. A branch to the sinoatrial node is given off early in this course. After giving off a rather sizable right marginal branch, the artery continues in the coronary sulcus to the posterior of the heart and turns down in the posterior interventricular sulcus as the posterior interventricular branch.

Left Coronary Artery

The left coronary artery arises from the left aortic sinus and passes anteriorly just to the left of the pulmonary trunk. In the cleft between the pulmonary trunk and the left auricle it divides into its anterior interventricular branch and its circumflex branch. The former passes down the anterior interventricular sulcus, supplying branches to both ventricles. The circumflex branch follows the coronary sulcus around to the posterior of the heart, giving off a prominent left marginal branch, and supplying a large branch to the posterior aspect of the left ventricle.

Venous Drainage

The venous drainage follows a pattern roughly corresponding with that of the arteries. The great cardiac vein originates from tributaries on the anterior aspect of the ventricles and courses upward in the anterior interventricular sulcus, reaching the coronary sulcus in which it runs around the left side, in company with the circumflex branch of the left coronary artery. On the posterior aspect of the heart this vein becomes continuous with the coronary sinus. In its course it receives a left marginal vein and the posterior vein of the left ventricle.

The coronary sinus lies in the posterior atrioventricular sulcus, passing from left to right, and enters the right atrium just to the left of the orifice of the inferior vena cava. Shortly before entering the atrium the coronary sinus receives the middle cardiac vein, which ascends in the posterior interventricular sulcus and the small cardiac vein. The latter vein usually begins on the right margin of the heart, associated with the right marginal artery. It ascends to the coronary sulcus, then runs with the right coronary artery posteriorly and joins the coronary sinus.

A group of three or four anterior cardiac veins is found on the anterior aspect of the right ventricle. These pass upward across the coronary sulcus, emptying directly into the right atrium. The oblique vein of the left atrium, although usually rather small, is of considerable interest in that it is the remnant of the left superior vena cava of the embryo. This vein lies on the posterior aspect of the left atrium in the cleft between the auricle and the left superior pulmonary vein. The site of its junction with the great cardiac vein signals the beginning of the coronary sinus. The oblique vein of the left atrium is continuous with a fibrous strand which attaches at its other end to the left superior intercostal vein. This strand is the ligament of the left superior vena cava. Occasionally obliteration of this system is incomplete, leaving the individual with a functional left superior caval vein.

Venae Cordis Minimae

A system of tiny channels within the musculature of the heart, opening directly into the chambers of the heart, is known as the venae cordis minimae. It would appear that blood flow in these "veins" might well be alternately away from and into the chambers.

Parasympathetic

Nerve Supply

The parasympathetic nerve supply to the heart is derived from the vagus nerves. The preganglionic fibers pass to the heart via the superior and inferior cervical cardiac and thoracic cardiac branches of the vagus on each side. After traversing the cardiac plexuses which lie in relation to the lesser curvature and posterior aspects of the aortic arch, these fibers terminate in synapses with postganglionic neurons which lie in the sulcus between the atria, on the base of the left auricle, and in the walls of the atria. Postganglionic fibers from these neurons end on the musculature of the sinoatrial and atrioventricular nodes.[1] Stimulation of these parasympathetic nerves results in a reduction of force and rate of the heart beat.

Sympathetic

Sympathetic innervation of the heart has its origin in the first five thoracic segments of the spinal cord. The second-order neurons of this system lie in the superior, middle, and inferior cervical sympathetic ganglia, as well as in the first four or five thoracic chain ganglia. Postganglionic fibers pass from all these ganglia to the cardiac plexuses on the aortic arch. Traversing these plexuses, the fibers terminate chiefly in the region of the atria, the sinoatrial node and atrioventricular node, and in relation to the coronary arteries. There is apparently a decided tendency for fibers of both the sympathetic and the parasympathetic systems to distribute principally to the side of the heart corresponding to the side of the body from which they arise. Sympathetic stimulus to the heart results in an increase in the rate and force of the heart beat.

With respect to the effect of the two systems on the coronary vessels conflicting evidence has been presented. It is perhaps most commonly held that vagal stimulation produces constriction and sympathetic stimulation results in dilatation of the coronary arteries. Certain investigators, however, have reported evidence to the contrary.[2]

Afferent Fibers

Considerable numbers of visceral afferent fibers accompany both autonomic pathways to the heart. Those accompanying the vagal branches have their peripheral terminals around the region of the roots of the great vessels. It is generally conceded that these fibers are concerned primarily with cardiac reflexes.

A rich supply of afferent fibers accompanies the sympathetic fibers in the middle and inferior cervical cardiac nerves as well as those fibers arising from the upper four or five thoracic segments of the sympathetic trunk. The cells of origin of these afferent fibers lie in the dorsal root ganglia of the upper five or six thoracic spinal nerves. On the right side, these pass to the sinoatrial node, the atrium and ventricle. Those from the left have their terminals in the walls of the left chambers, the interatrial septum, the pulmonary veins, and the atrioventricular node. The association of these afferents with the upper thoracic nerves accounts for the referral of cardiac pain to regions of the body innervated by these nerves, notably the ulnar aspect of the upper limb and the upper part of the thorax.

Sinoatrial Node

The intrinsic rhythmic activity of the heart muscle is initiated in a small mass of specialized myocardial tissue which lies in the right atrial wall in the cleft between the superior vena cava and the right auricle. The contraction which begins in this sinoatrial node spreads through the atrial musculature, and thus reaches another node of similarly specialized tissue, the *atrioventricular node.* This lies in the interatrial septum just superior and anterior to the opening of the coronary sinus into the right atrium. From this node the contractible impulse is conducted to the ventricular musculature by a neuromuscular bundle, the *atrioventricular bundle.* This bundle of fibers passes through the right atrioventricular fibrous ring (Fig. 2) and runs anteriorly in the upper margin of the muscular interventricular septum (just inferior to the septum membranacea). Here the bundle divides into two branches (Fig. 3), one of which passes down each side of the interventricular septum just under the endothelium. The right branch courses downward, passing in the septomarginal or moderator band to the anterior papillary muscle, distributing to the anterior ventricular muscle. The wide flat left septal branch of the bundle runs downward on the septum, supplying the papillary muscles and general musculature of the left ventricular wall.

In many mammals the atrioventricular bundle is a very discrete, specialized band of tissue with a distinct sheath of connective tissue. In man, however, the bundle is apparently not so definitely specialized. In fact some investigators have failed to demonstrate the presence of specialized fibers at all.[3] Others[4] observed at least a few Purkinje* fibers in over one half of their human specimens. They demonstrated that such fibers in man "have different staining properties, a smaller mean diameter, and variable amounts of myofibrillae." Their conclusion was that these differences accounted for the discrepancies of interpretation by various investigators.

This review is only a brief presentation of the major aspects of cardiac anatomy. If, however, it supports or gives emphasis to the presentations of other contributors which follow, its purpose will have been accomplished.

Roentgenographic Data on One Female Mummy

Fourth in Series

Among several Egyptian mummies photographed and studied in detail was that of a woman. Aside from slight but negligible deviations from normality, her head showed a cloudy granulation of the cortex, indicating osteosclerosis due to a healed infection; it also revealed edentia except for five mandibular teeth, probably due to absorptive osteitis.

Her torso and limbs presented no abnormalities except marked kyphosis of the thoracic vertebrae; spondylitis deformans resulting from spinous processes on the mid-dorsal vertebrae and in the lumbar region; partial coalescence of some articular surfaces of the vertebral arches; and evidences of ateriosclerosis in the lumbar ligaments, the rib bodies, the ventral blood vessels of the right scapula, and the radial artery near the wrist.

This lady was doubtless somewhat senile — physiologically if not chronologically.

Illustrations of the roentgenograms of this female mummy with accompanying texts appear in the Anthropological Memoir of the Field Museum of Natural History, Volume III.

Heart Sounds

Simple
and
Yet
Complex

ROBERT L. GRISSOM, M.D.*
Omaha, Nebraska

THE HEART SPEAKS a language to us through its sounds, whenever we listen to it. This language has inflection and pitch; sometimes it sounds ominous and sometimes it seems to jump for joy. Although this language can tell us much, most of us pay little attention to the "lubb-dups," giving preferential attention to the murmurs if they exist. It is my purpose to ignore the murmurs today and to examine each of the familiar heart sounds individually. Also at the bedside we should focus our attention on one sound at a time in order that their language may best be understood by us.

Most physicians will think of only two sounds, the familiar "lubb-dup" in a patient's heart sound findings; but really there are four major sounds, each of which has at least two and some four components. The four sounds may be schematically represented by a diagram[1] as in Figure 1.

The Fourth Heart Sound

Here it can be seen that the fourth sound has both a right atrial and a left atrial component which arise from the tension of the heart wall as atrial contraction forces a final jet of blood into the already distended ventricles. Although regularly seen with sensitive electronic equipment, it is generally inaudible with the ordinary stethoscope. When heard, however, it is a single sound with low frequency and low intensity vibrations of short duration. It can be identified most easily when there is a partial atrioventricular block or a complete heart block. Occasionally in systemic hypertension it may be heard. In one study[2] over 50 per cent of normal persons over 80 years of age had an audible fourth sound. It becomes louder when heart failure is present with an increase in venous pressure and enlargement of the heart. In this circumstance this fourth heart sound will be called an "atrial gallop."

The First Heart Sound

The first sound, which we shall consider next, has been the least understood of all sounds. Normally it is longer in duration and lower in pitch than the second heart sound. Yet this is not always the case. In embryocardia, for example, the first and second sounds are quite similar and the intervals between them approximately the same. In such a circumstance one may find the technique of "inching" down from the base to the apex helpful in timing the heart cycle.

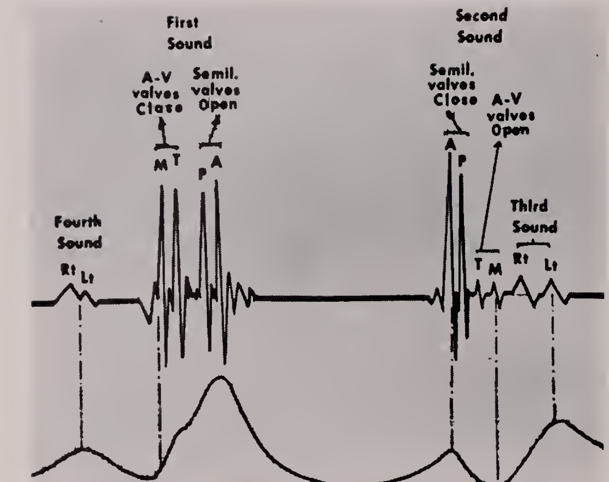

Fig. 1 — From Luisada, by permission. The linear or apex cardiogram, showing only the low frequency impulse, is drawn in the lower trace for reference.

Recent research has revolutionized our interpretation of this sound. Previously most clinicians believed the first heart sound had two principal components, due to closure sequentially of the mitral and tricuspid valves. When splitting occurred it was interpreted as asynchronous closure of these two A-V valves and suggestive of a bundle branch block. There is much evidence now to indicate that the mechanical event of closure of the mitral and tricuspid valves makes up little or none of the first sound. In the experimental dog, for example, the A-V valves have already closed before the rapid vibrations of the first heart sound occur. Intracardiac sound recordings have shown that the majority of the sound vibrations are associated with the rapid rise of pressure in the left ventricle. In the normal heart neither the right ventricle nor the tricuspid valve contributes a great deal to these sounds externally. In most instances in the normal heart the left-sided events precede the right-sided events, although sometimes they coincide. In any case, the very last component can be shown to coincide with ejection into the aorta and pulmonary artery and is principally due to vascular vibrations.

This explanation of the first sound has been dealt with somewhat in detail, since it is possible to confuse initial portions of this sound with a presystolic murmur or to confuse ejection clicks with the fourth component. "Splitting" of the first sound is much less significant as a clinical phenomenon than splitting of the second sound, which will be discussed later. More important than splitting of the first sound is the characteristic "snapping" of the sound of mitral stenosis.

Snapping Sound of Mitral Stenosis.

This has been shown to be due to tension and vibrations of the mitral leaflet and is often a first clue to the examiner that he is dealing with mitral valvular stenosis. Those who do phonocardiograms in preoperative evaluation of mitral disease have found it useful to measure the time from the beginning of the Q wave in the electrocardiogram until the mitral valve closure sound as an index of the severity of mitral stenosis. The longer the interval the "tighter" the stenosis,[3] as a rule.

When there is insufficiency of that valve the first sound progressively diminishes in intensity and may even be "masked" or swallowed up in the murmur. It has been a clinical observation that first-stage A-V block also resulted in a diminished first heart sound, but the best correlation here seems to be myocardial weakness and a slow rise of the intraventricular pressure. Other causes for a prominent first heart sound are anemia, thyrotoxicosis, exercise or increased cardiac output from any cause.

The Second Heart Sound

The second heart sound is generally more admired by clinicians than any other of the sounds. And for good reason! In young persons it is frequently split with inspiration. Much attention is paid to this phenomenon as a teaching device for sophomore medical students in physical diagnosis.

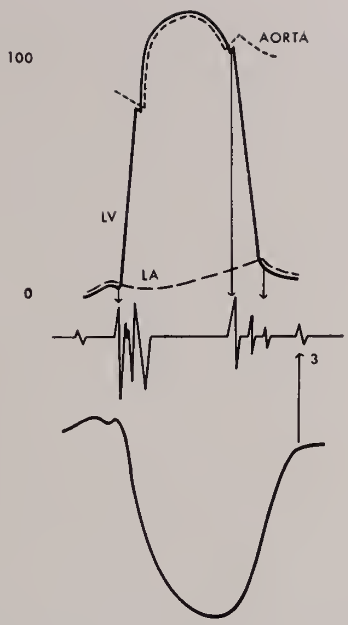
Influence of Inspiration

The second sound splits into the two components when the pulmonary valve closes appreciably after the aortic valve, which it tends to do after inspiration gives an increased right ventricular stroke volume. More blood has been aspirated into the chest and expelled into the pulmonary artery, so that right ventricular systole has been prolonged more than left ventricular systole. Considerable attention has been given to "paradoxical splitting," which, in most cases, is due to unusually late closure of the aortic valve and thus a reversal of the usual relationship. At the same time pulmonic closure, reflecting as it does the duration of right ventricular systole, still lengthens with inspiration and shortens with expiration. Because of its reversed position with respect to the aortic sound, however, the pulmonic closure sound splits from the aortic valve on expiration, not inspiration. This can occur with left-bundle branch block and sometimes in severe aortic stenosis and hypertension.[4] The detection of this gives the doctor who hears it a "one-upmanship" standing.

Pulmonary Component

Close attention ought to be paid to the pulmonary component of this second sound, which is usually best heard in the left second interspace, as an index of pulmonary hypertension. This is the only auscultatory sign of the lesser circuit blood pressure the clinician has and, when loud, is quite reliable for the diagnosis of pulmonary hypertension. It is helpful especially in congenital heart disease and in rheumatic mitral stenosis. Similarly a loud aortic closure sound will best be heard in the right second interspace. It will be loud and sharp in systemic hypertension and in dilatation of the ascending aorta.

Following shortly after this second sound, when there is mitral stenosis, a vibration may often be distinctly heard as the "opening snap" of the mitral valve. It is not listed as one of the "big four" of the heart sounds, but it might well be, since it is a discrete sound and not a murmur. It is shown in Figure 1 as "A-V valves open." The tensing of the valve and its flexibility are important. A skilled examiner can predict from the "sharpness" of the sound whether the valve will be successfully fractured by a "blind" approach at mitral valvotomy. If it is a dull sound, he will predict a less satisfactory result of heart surgery by this technique.



—Time-pressure relationship of the left side of the circulation (above) with time-volume relationship of the left ventricle (below). The third sound occurs at the end of period of rapid filling of the ventricle.*

Fig. 2

In patients with congenital heart disease, the heart sounds have great importance because pulmonary hypertension frequently occurs and produces the loud pulmonary second sound. Also shunts can result in large ventricular flows so that third sounds also are readily heard. One phenomenon that deserves special mention is the "fixed splitting" of the second sound in patients with atrial septal defect. This is a valuable sign. While it may also be found in ventricular septal defect, it is not difficult to distinguish this condition. I have chosen an example to illustrate this by a different means of recording secondary heart sounds, the so-called spectrophonocardiogram. In this type of recording, intensity is reflected by the density of the tracing, and sound frequency by the height. In Figure 3 a double or split second sound[6] is seen in all four areas where it was recorded. This is due to delayed pulmonary closure because of the large right ventricular ejection volume. Although not shown here the splitting was seen regardless of the respiratory cycle and is therefore spoken of as "fixed." The right ventricular flow is so large at all phases that the usual inspiratory increase in flow does not further prolong systole. It is useful to record "fixed splitting" on a phonocardiogram when it is found, but the clinician usually can make the diagnosis of fixed splitting without the recording machine.

---

*From Stern, by permission.

The Third Heart Sound

The third heart sound is due to rapid filling of the ventricles and coincides with a filling wave shown in the lower part of Figure 1 as the linear apex cardiogram. This sound may normally be heard in most children but gradually disappears in the young adult, so that it is seldom heard as a physiological phenomenon in the 40s or beyond. When there is heart enlargement, its presence at the same point in the cycle can reliably be interpreted as a ventricular gallop. As such it has ominous significance, often implying heart failure. Also, in marked mitral valve insufficiency when there is a large inrush of blood from the left atrium to the left ventricle, a third sound may be produced. As a gallop sound, however, it usually signifies ventricular dilatation. In the older adult it is often found with arteriosclerotic heart disease in failure. It may be found with anginal pain, only to disappear when the angina leaves. As a low pitched sound, its presence is often missed by the casual observer. Dr. Paul White has shown that it is one of the most significant findings in diseased hearts, yet one that is frequently missed.

Figure 2 will show these sounds[5] plotted against the left ventricular, left atrial and aortic pressure phenomena above the phonocardiographic tracing, with the time-volume relationship of the left ventricle below. A similar diagram could be drawn for the right ventricle with the ventricular systolic pressure levels about one fourth those of the left side. The two sides are so nearly alike in sound production that one illustration serves for both.

In the presence of a tachycardia and heart failure the third and fourth sound "gallops" may be heard as a single set of vibrations known as a "summation" gallop. An illustration of this was shown where the summation gallop was heard when a patient with heart failure was first examined. The next day when the heart rate had slowed, the third and fourth sounds (ventricular and atrial gallops) were heard separately.

The tracing in Figure 3 also shows a systolic click (SC) in the third auscultatory area along the left lower sternal border. Such sounds have no known clinical significance and are thought to arise from the pericardium. Loosely they may be called "systolic gallop" sounds, which is unfortunate because of the serious nature of other gallop sounds. Systolic clicks must also be differ-

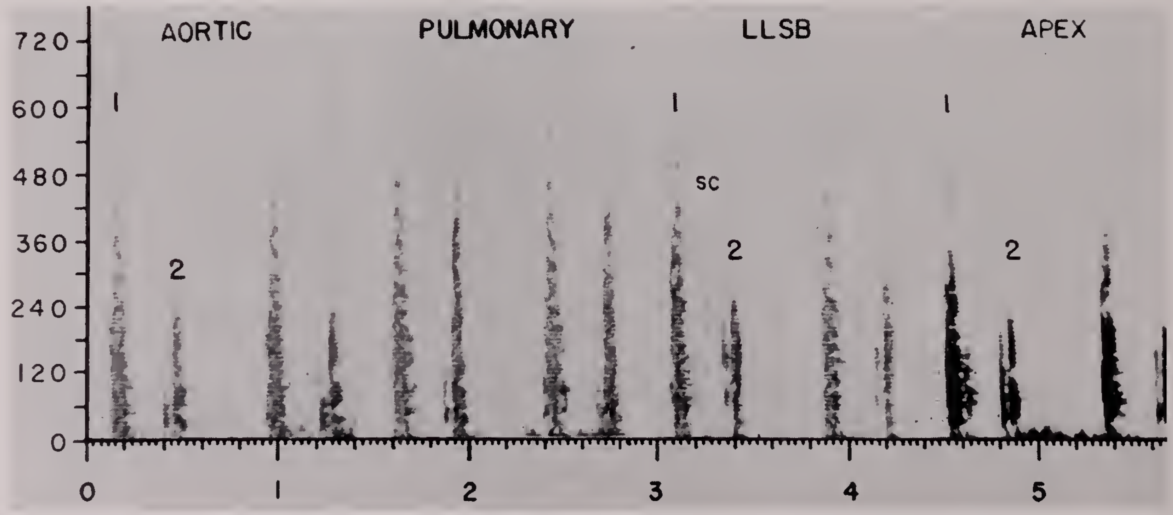


Fig. 3 — The spectral phonocardiogram in a patient with atrial septal defect. The "split" second sound is shown at a constant interval in all locations. The pulmonic closure component is especially loud in the pulmonary area. SC = systolic click. From Stern, by permission.

entiated from "ejection sounds," also called "ejection clicks," which can arise from vibration in a dilated pulmonary artery with the large pulmonary blood flow of an atrial septal defect. Such ejection sounds may also arise in a dilated aortic wall.

Conclusions

This review was intended to show that the heart sounds are no more than simple vibrations of valves or heart walls or the great vessels. Yet they are incompletely understood and for that reason especially are assumed to be complex. Often they yield information more meaningful than murmurs. How else can one simply determine pulmonary arterial hypertension, or a stenotic mitral valve which will respond to valvotomy, or early congestive failure? But the heart sounds must be sought out individually in the patient and studied carefully. It is interesting to hear their language too. And they will speak much more clearly to us if only we will listen to what they have to say.

IT'S THE LAW

Settlement Reported in Cardiac-Arrest Case

A settlement in the total amount of $300,000 has been reported in a case in which a hospital in Nassau County, New York, a surgeon, and an anesthesiologist were charged with negligence in the care of a ten-year-old boy who suffered a cardiac arrest. The arrest occurred following surgery while the patient was in the hospital recovery room.

It is reported that the boy is a permanent invalid, suffering mental retardation, loss of vision, and cerebral palsy. It was contended that the surgeon and the anesthesiologist were negligent in not remaining with the patient in the recovery room and in failing to make sure that the recovery room was properly equipped and staffed. It was also alleged that the hospital was negligent in failing to maintain an adequate recovery room and to enforce proper rules for the conduct of surgical procedures, and that the nurse, who was alone in the recovery room, was inexperienced and failed to detect the cardiac arrest for several minutes.

Ventricular

THE NATURE of the heart's rhythmical action has aroused man's interest for centuries. According to Scherf and Schott[1] arrhythmical activity of the heart had been noted as far back as the sixth century B.C. Until the end of the last century discussions of the cardiac arrhythmias were largely descriptive in nature, and inferences about the significance of the arrhythmias were speculative. Due largely to Engelmann's[2] significant work in 1895 on the refractory period and compensatory pause, understanding of the physiology of arrhythmias reached a level applicable to clinical interpretation and resulted in attempts at classification.

Present interpretation classifies abnormal cardiac rhythms into two broad categories: (1) disturbances in impulse conduction, and (2) disturbances in impulse formation. In the latter category, abnormal impulses may arise in the atria, the A-V node and bundle, or in the ventricles. Recurrence of such abnormal impulses constitutes an abnormal rhythm. Such rhythms may be *passive* (arising as a result of depression of the sinus pacemaker), or they may be *active* (arising as a result of an ectopic focus of impulse formation). The present discussion is concerned only with those arrhythmias designated as active, when some local condition exists which serves to initiate an abnormal impulse. It is generally agreed that the local conditions which initiate abnormal impulses affect one or the other of the two basic properties of the heart: irritability and rhythmicity.

Enhanced Rhythmicity as a Factor in Ventricular Arrhythmias

The property of rhythmicity is especially well developed in the sinus venosus node which acts as the pacemaker of the heart.[3] Intracellular recordings have shown that in cells of the sinus venosus node a slow diastolic depolarization takes place.[4] When the depolarization reaches a critical threshold potential a propagated action potential is initiated which spreads over the entire heart. Most attempts to explain the spontaneous depolarization of pacemaker cells have been based on the Hodgkin concept of membrane permeabilities.[5] As suggested by Weidmann,[6] diastolic depolarization could be due to a decrease in potassium permeability, to an increase in sodium permeability or to a reduction in the activity of the sodium pump (see later). In any event, diastolic depolarization represents an alteration of the cell membrane such that sodium leaks into the fiber. The critical threshold potential is the value at which the sodium inward current exceeds the outward diffusion of potassium, resulting in a sudden and complete depolarization.

It is plausible to explain some forms of ventricular arrhythmia on the basis of an

Arrhythmias*

W. O. READ, Ph.D.**
Vermillion, South Dakota

enhancement of rhythmicity, i.e., an ectopic focus in the ventricle where local changes act to periodically depolarize the cell membrane and initiate an independent automatic rhythm. That the ventricular tissue has inherent rhythmicity is implied in the observation of Patten and Kramer[7] on the embryonic chick heart. In their preparation, the first heart beat began in the ventricular tissue. This pacemaker activity was subsequently taken over by the more rapid atria and then by the S-A node (sinus venosus) as development proceeded. Hecht[8] also shows, in his Figure 15 recorded at high speed, a small diastolic depolarization in frog ventricular fibers suggesting that pacemaker activity is a normal though latent property of ventricular fibers. Enhancement of latent rhythmicity could account for ventricular extrasystoles, although Hoffman and Cranefield[9] state that they have never observed pacemaker activity in ventricular fibers (dogs) even during ventricular fibrillation. Nevertheless, it is probable that in the experimental preparations, irritability is more prone to be affected than is latent rhythmicity. Therefore, it is not surprising that pacemaker activity is not encountered in ventricular intracellular recordings. Pacemaker activity is regularly observed in Purkinje fibers,[6] and Katz[10] is of the opinion that all ventricular extrasystoles arise from terminal Purkinje network fibers. Certainly enhanced rhythmicity of ventricular fibers should give independent ectopic rhythms with rates of 30 to 40 per minute. Di Palma and Schultz[11] point out the necessity for this slow rate. In rare instances this does occur (parasystole), in which an independent pacemaker in the ventricle exists with the normal sinus pacemaker. The beats due to the ectopic pacemaker become manifest when they fall on nonrefractory ventricular tissue. These ectopic beats would, therefore, occur in various phases of the cardiac cycle and bear no relation to the sinus beat. When they occur at the same time as the sinus beat, they may fuse with the normal beat.

Influence of Calcium

The reason for development of enhanced rhythmicity is conjectural and no real explanation can be offered. However, calcium deficiency is known to favor automatic impulse formation,[12] and local changes in calcium may be involved. Also, some observations made by Burn[13] on the synthesis of acetylcholine by heart tissue and the relation of the cellular concentration of acetylcholine to automatic impulse formation may have a direct bearing on development of ectopic pacemaker in cardiac tissue. It is difficult to explain, as Kaufmann and Rothberger[14] pointed out in 1920, how the ectopic center is protected from depolarization by the more frequent sinus venosus nodal impulse. Nevertheless, such directional blocks do exist normally in the conduction tissue, as when ventricular extrasystoles are prevented from activating the atria. The physiology of this phenomenon is coming under close scrutiny and an answer may be forthcoming.

Altered Irritability as a Factor in Ventricular Arrhythmias

Unlike the independent rhythm of parasystole, the more common arrhythmias are those in which the ectopic beat follows the preceding beat at a constant and fixed interval. The preceding beat initiates the abnormal beat. The abnormal beat is therefore, a passive phenomenon, the "forced" contraction of Lewis,[15] and a true premature ventricular contraction. In support of this is an interesting experiment by Goldenberg and Rothberger[16] in which an arrhythmia with coupling was produced in dogs by the intravenous injection of strophanthin combined with inhalation of a mixture of 30 per cent CO_2 in O_2.

Vagal stimulation produced cardiac standstill. No ventricular beats occurred. Had an independent rhythm existed in the ventricle it should have persisted during vagal stimulation. Scherf[17] did a similar experiment in rabbits with the same results, showing that each premature contraction was precipitated by and dependent upon the preceding beat. There are two main theories advanced to explain the mechanism underlying premature contractions with fixed coupling: (1) origin of the impulse in an ectopic focus of high excitability, and (2) origin of the impulse by re-entry into an island of previously depressed tissue. Both mechanisms depend on the preceding beat for their existence.

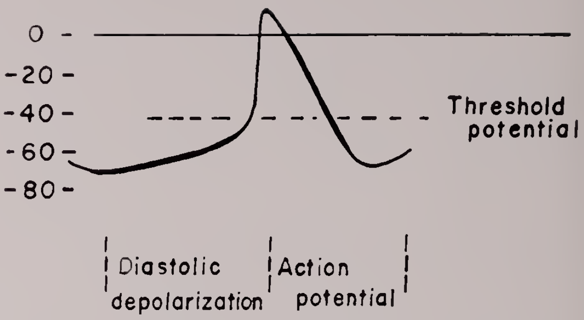

Fig. 1 — The action potential of pacemaker fibers of the S-A node, showing slow diastolic depolarization which, when reaching a critical threshold potential, initiates a propagated action potential.

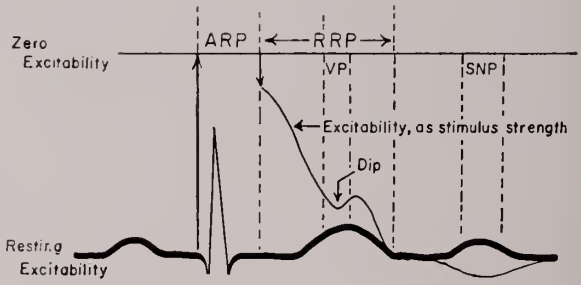

Fig. 2 — Representation of the excitability of heart muscle during one cardiac cycle. The ECG isoelectric line is plotted on the line representing resting excitability. During inscription of the QRS (depolarization) the excitability decreases to zero. Thereafter, recovery returns gradually. Excitability curve is drawn as the stimulus strength necessary to excite. The recovery period may be followed by a period of supernormality. ARP-absolute refractory period. RRP-relative refractory period. VP-vulnerable period. SNP-supernormal period.

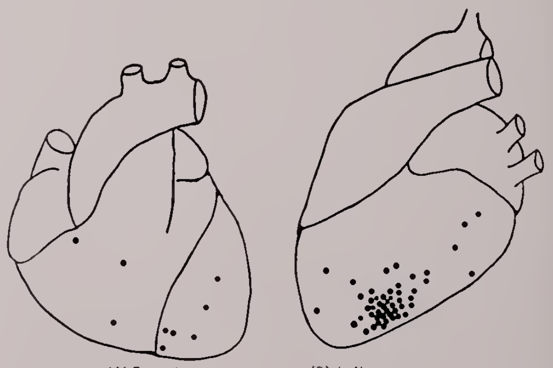

(A) Frontal view (B) Left view

Fig. 3 — Drawing of a dog heart in the frontal and left view on which are plotted the origin of all epinephrine-induced ventricular premature contractions found in 59 trials on 14 dogs. There is a concentration of ectopic beats arising in the posterior aspect of the left ventricle near the apex.

Supernormal Phase — U Wave

The essential feature of the former is that the premature contraction is generated in an ectopic focus where local changes from the preceding impulse produce a temporary rise in excitability. That such a rise in excitability is possible was demonstrated by Adrian[18] in 1920 for frog heart. It is called the supernormal period, and Adrian noted that it is accentuated by acid or fatigue. Hoff and Nahum[19] demonstrated a supernormal period in mammalian ventricle (cat) under barbiturate anesthesia. The supernormal phase corresponds to the U wave of the electrocardiogram and, according to Nahum and Hoff,[20] is the period when most premature ventricular contractions occur. Lepeschkin[21] has brought together much evidence relating the U wave of the surface electrocardiogram to the supernormal phase of ventricular excitability and to the initiation of coupled premature contractions. He finds that factors which increase the amplitude of the U wave facilitate the appearance of coupled premature contractions: epinephrine, digitalis, calcium, hypopotassemia, acidosis. Scherf and Schott[7] offer a mild objection to the view that the supernormal period is responsible for initiating ventricular premature contractions, at least the common variety with fixed coupling, on the grounds that such a period cannot be regularly demonstrated in all hearts. Wolferth[22] also raised a similar objection. In addition, application of veretrine, which prolongs the negative afterpotential (the supernormal period) and precipitates ectopic beats, does not always produce fixed coupling. Lepeschkin[21] also notes that quinidine suppresses coupled extrasystoles, yet at the same time increases the U wave (supernormal period). While these objections are valid and must enter into any argument relating the supernormal period to coupled premature contractions, much can be said in favor of the supernormal period as providing a focus for initiation of premature contractions.

Of some relevance to this problem are some experiments performed in our own laboratory. We wished to decide whether a ventricular premature contraction arose from a specific and predictable focus in the ventricle. In order to test this, spatial vectocardiograms of the dog, one from the frontal plane and one from the sagittal plane, were visualized on separate oscilloscopes and the tracings photographed simultaneously. The vector loops were enlarged and transposed to the sides of a large plastic box ruled in coordinates. This allowed us to locate the origin of the ventricular complex. The procedure was carried out a total of 59 times in 14 dogs. Figure 3 illustrates the points of origin of all ventricular premature contractions. The majority originated in a circumscribed area of the left ventricle, posteriorly near the apex. We attempted to explain why premature contractions arose from this circumscribed area of the left ventricle. Plastic casts of the arterial tree showed no deficiency of coronary blood flow to this area. Chemical determination showed no difference in epinephrine, norepinephrine or total catecholamine content. There was a slight difference in the isethionic-acid level, but this was of questionable significance. Of some relevance to the results is the fact that this area corresponds to the point of attachment of the large papillary muscle of the left ventricle, and electrocardiograms showed that the ventricular premature contractions arose during the inscription of the U wave.

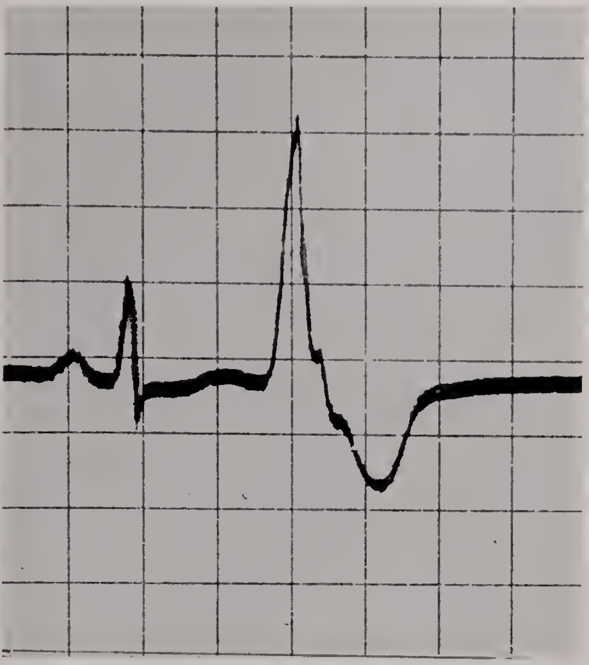

Fig. 4 — Ventricular premature contraction arising from the U wave. Record taken from a 60-year-old male with some indication of ischemia of the left ventricular wall.

Influence of Stretching

The observation of Dudel and Trautwein[23] indicates that stretching increases the negative after-potential of cardiac muscle. Therefore, as Lepeschin[21] points out, the negative after-potential (supernormal period, U wave) would be expected to be highest in parts of the ventricle subjected to greatest stretch. The papillary muscles bear the entire systolic ventricular pressure that is exerted on the atrioventricular valves. Indeed, Furbett et al.[24] noted that the U waves are most

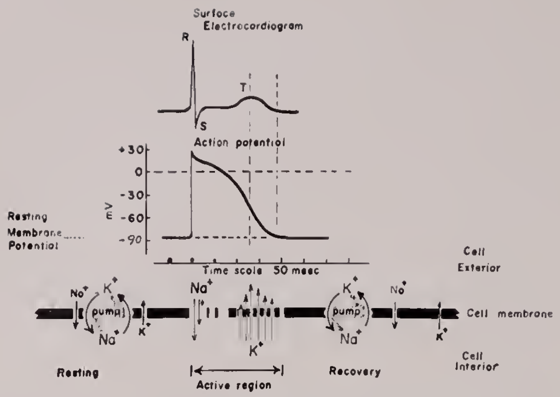

Fig. 5 — Schematic representation of the mechanism responsible for the membrane resting and action potential denoting the ion movements responsible for the electrical variation. At the top, the surface electrocardiogram is drawn in relation to a cell-action potential. During depolarization Na+ moves into the cell and during repolarization K+ moves out of the cell.

prominent on the ventricular surface opposite the insertion of the papillary muscles. Increase of the supernormal phase of ventricular repolarization due to stretching would appear to be a reasonable explanation for the origin of ventricular premature contractions in the small circumscribed area defined in our experiments. Indeed, stretch or distention of the cardiac chambers during hypertension or congestive heart failure is a common cause of cardiac arrhythmias.[25]

Depressed Heart

It is an important observation that coupled arrhythmias also develop in hearts which are depressed. A re-entry mechanism is offered to explain such coupled rhythms. This mechanism predicts that islands of cells exist in which recovery is slower than normal. The normal impulse passes around the depressed area but re-enters it at a later time in recovery, i.e., when the island of tissue has sufficiently recovered to permit entry. The re-entry then serves as a locus for initiation of a second beat. In 1940 Wiggers and Wegria[26] reported that single induction shocks applied during the vulnerable period (that period just preceding the peak of the T wave[27]) could, depending on the strength of the shock, produce single or multiple premature contractions or fibrillation. Hoffman et al.[28] relate the vulnerable period to the major dip in the recovery curve, and Brooks et al.[29] explain the vulnerability of the ventricle during this stage of recovery as due to the prolonged recovery of a localized area which allows for re-entry of the normal impulse. It seems that factors which depress the heart may produce localized areas of depression with prolonged refractory periods or decreased conduction allowing for re-entry and development of coupled beats.

Ions in Ventricular Arrhythmias

Inasmuch as premature contractions seem to develop during the recovery (repolarization) phase of myocardial activity, it is pertinent to inquire into those events which are happening during this time. The irritable property of the heart cell is dependent upon the functional characteristics of the cell membrane. The functional properties of the membrane have been deduced through an explanation of the mechanism underlying three fundamental observations. *First,* the cell membrane separates extracellular fluid of high sodium (Na^+) and low potassium (K^+) from an intracellular fluid of high K^+ and low Na^+. *Second,* Na^+ and K^+ are continuously diffusing into and out of the cell, i.e., the cell membrane is slightly permeable to Na^+ and K^+, and more so to K^+ than to Na^+. *Third,* an electrical potential of 80 to 90 millivolts exists across the cell membrane of the resting cell, with the inside of the cell negative to the outside. The reversal of the electrical potential difference across the cell membrane during activity produces the "action potential." The present concept of resting and membrane action potential is summarized in Figure 5.

Sodium-Potassium Transport Mechanism

The bold dark line represents the cell membrane. This membrane is slightly permeable to Na^+ and K^+, and more so to K^+ than to Na^+. In the resting membrane, as Na^+ diffuses into the cell it is actively transported to the outside by means of a special Na^+ transport mechanism located in the membrane. As Na^+ and K^+ diffuse into the cell and Na^+ is actively extruded, this leaves an accumulation of K^+ inside the cell. The rising concentration of K^+ inside the cell forces K^+ to diffuse away from this high concentration to the outside of the cell, leaving a residual negative charge behind on the inner surface of the membrane. When the residual negativity pulling K^+ into the cell is equal to the force of the K^+ concentration tending to force K^+ out of the cell, there is no *net* movement of K^+; although K^+ is constantly moving into and out of the cell. The resting membrane potential is determined by the ratio of the K concentration and is negligibly affected by the Na concentration. Figure 5 depicts extrusion of $Na^+ - K^+$ exchange pump. The action potential (moving from right to left) represents a sudden reversal of electrical sign (a change from 80 to 90 mV inside negative to 20 to 40 mV inside positive) due to a sudden and large increase in membrane permeability to Na^+, and Na^+ moves into the cell. A plateau near zero potential (slow repolarization) follows, at the end of which the electrical potential rapidly reverts to the resting level (rapid repolarization) due to an increase in the membrane permeability to K^+, and K^+ moves from the inside of the cell to the outside. During the action potential the cell has gained a small amount of Na^+ and lost a small amount of K^+. The $Na^+ - K^+$ pump then extrudes the Na^+ gained during depolarization and reclaims the K^+ lost during repolarization.

Inasmuch as ventricular premature contractions develop during the repolarization phase of myocardial activity, it is reasonable to relate such arrhythmias to the efflux of K^+ which occurs at this time. The apparent relationship of myocardial potassium loss to cardiac arrhythmias is well documented, and potassium administration is known to suppress ventricular arrhythmias. The arrhythmias accompanying toxic doses of the digitalis glycosides apparently are related to the large loss of K^+.

Influence of Taurine

In our own laboratory we were able to show that the compound taurine (2-aminoethanesulfonic acid) prevented the loss of cell K^+ from heart slices incubated in the presence of "toxic" amounts of epinephrine or digoxin.[30] Indeed, the presence of taurine caused an accumulation of cell potassium (Table 1).

We were interested in determining whether the effect of taurine in restricting K^+ loss from heart slices would be effective in suppressing epinephrine or digitoxin-induced ventricular arrhythmias in the intact dog heart. Acute experiments performed on anesthetized, vagotomized dogs showed that taurine was effective in suppressing the premature ventricular contractions caused by adequate doses of epinephrine. Additional experiments showed that taurine was effective in abolishing the cardiac arrhythmias produced by either acute or prolonged chronic administration of digitoxin.[31] Figure 6 is a record from this series. Taurine appeared

TABLE 1

Effect of Taurine on the Intracellular Potassium Content of Dog-Heart Slices

Experimental Condition	Intracellular K mEq/λ cell H_2O
Control (18)[a]	144 ± 0.08[b]
Epinephrine, 10^{-4}M (12)	139 ± 1.24
Taurine, 10^{-4}M plus epinephrine 10^{-4}M (9)	163 ± 0.85
Digoxin. 1.25 X 10^{-4}M (8)	139 ± 0.72
Taurine, 10^{-4}M plus digoxin, 1.25 X 10^{-4}M (8)	153 ± 1.31

TABLE 2

Effect of Taurine and Chemically Related Compounds on the Dose of Digoxin Required to Produce Arrhythmias

Compounds adjusted to pH 7.4 infused at constant dose of 3.3 μM/kg/min.	Total dose of digoxin required to produce arrhythmias when injected in a constant amount of 1 μg/kg/min.
	μg/kg
Control	119 ± 3.7
Taurine (2-aminoethanesulfonic acid)	180 ± 5.3
3-Aminopropanesulfonic acid	150 ± 9.0
Ethanesulfonic Acid	143 ± 8.4
Ethylamine	136 ± 7.5
Sulfanilic Acid	120 ± 4.6

to be the most effective of several chemically related compounds in protecting the heart against digoxin-induced arrhythmias. Table 2 gives the results of acute experiments in which test compounds were administered intravenously at the same time as the toxic dose of digoxin (as judged by runs of premature contractions). While ethanesulfonic acid and ethylamine raised the toxic dose of digoxin, both compounds were ineffective in reverting an established digoxin-induced arrhythmia to a normal sinus rhythm, whereas both taurine and 3-aminopropane were effective. Additional work on intact, anesthetized dogs showed that taurine prevented the large efflux of potassium from the heart which accompanies large doses of epinephrine[30] (Figure 6).

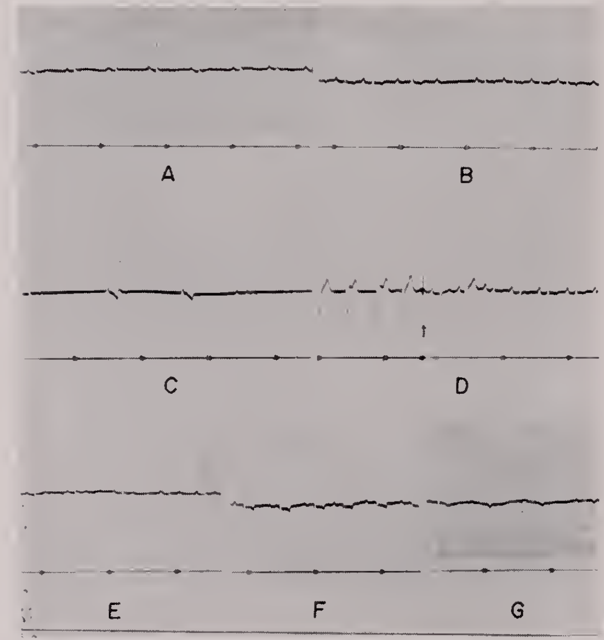

Fig 6 — Sections of the electrocardiogram (Lead II) to demonstrate the effect of taurine in inhibiting toxic manifestations of chronic administration of digitalis in trained, unanesthetized dogs. In this dog a total of 732 μg of digitoxin (chrystodigin, Lilly) had been administered orally over 29 days. A — control before digitoxin administration. B — 25 days of digitoxin administration, showing prolonged P-R interval, beginning A-V dissociation. C — three hours after B, showing complete A-V dissociation. D — 29 days of digoxin administration, premature contractions. At the arrow, 10 m mole of taurine per kg. was administered i.v. over a 30 min. period. Conversion to a normal sinus rhythm begins in about 5 min., when short runs of normal rhythm appear, and is virtually complete in 15 min.
E, F and G are 2 hours, 24 hours and 30 days after taurine. Chart speed 25 mm. per sec. Standardization 1 mV = 5 mm. (From Read and Welty, Rev Canad Biol Symp 1965).

Antiarrhythmic Drugs

The antiarrhythmic drugs, quinidine, procaine amide and sympathomimetic amines operate to retard the potassium efflux* which precedes cardiac arrhythmias. Quinidine appears to depress K efflux,[32] although the effect may be secondary to a depression of inward Na movement.[33] Gold and Carday[34] proposed the use of vasopressor agents in cardiac arrhythmias and suggested that the antiarrhythmic property was due to their ability to maintain coronary blood flow. However, Robertson and Peyser[35] showed that small doses (less than 5 μg/kg) of epinephrine increase the intracellular K^+ of myocardial cells (confirmed by Wadell).[36] Stafford,[37] in a detailed study, also showed that adrenalin (2 X 10^{-8}M) increased the uptake of K in the spontaneously beating

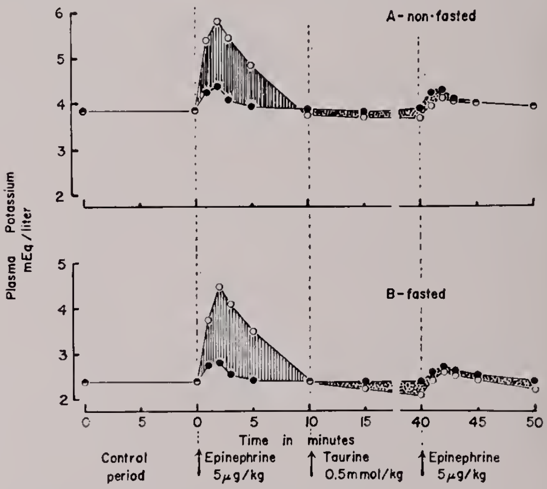

Fig. 7 — Plasma K levels of blood simultaneously drawn from the coronary sinus and the arch of the aorta in nonfasted and 12-hour-fasted dogs. Note the difference in the K levels during the control period of nonfasted and fasted dogs. Intravenous injections were made at the times indicated by the arrows. The cross-hatched area represents loss of K^+ from the heart; the stippled area represents uptake of K^+ by the heart. Taurine administration prevented the egress of K which accompanies adequate doses of epinephrine. Immediately following epinephrine, there is a rapid uptake of K^+ by the heart followed by an efflux. The uptake is not shown due to the spacing of the samples (From Read and Welty, Rev Canad Biol Symp 1965).

---

*See Test Your Word Score Page 1333.

auricles. In intact dogs in which the coronary sinus blood is continuously monitored, we have consistently observed that 1 μg of epinephrine per kg. causes an uptake of myocardial potassium. Reasoning that epinephrine should block K^+ egress, Regan et al.[38] reported that a sustained infusion of epinephrine in intact dogs prevented the arrhythmias due to strophanthidin. These authors felt that the antiarrhythmic property was related to the prevention of myocardial potassium loss and not to an effect on arterial pressure and coronary blood flow.

All of the antiarrhythmic drugs are known to have important side effects, and potassium administration is not without hazard. It is possible that taurine, a nontoxic and natural substance in the heart, may prove effective in the control of digitalis intoxication and in certain forms of ventricular arrhythmias.

Summary

Ventricular arrhythmias may be produced by two basic mechanisms: development of an ectopic focus of impulse formation and re-entry into an area of depressed conduction. Ventricular arrhythmias are commonly associated with those phases of repolarization corresponding to the supernormal phase (U wave of electrocardiogram) or terminal part of the relative refractory period (T wave of electrocardiogram). Such arrhythmias are correlated with a large myocardial potassium loss. Substances which restrict myocardial potassium loss appear to be effective agents in suppressing ventricular arrhythmias. Taurine, a nontoxic and natural substance in the heart, appears to have antiarrhythmic properties due to its ability to retard myocardial potassium loss.

FANCONI'S SYNDROME

This syndrome may include a wide variety of birth anomalies and it is thought that the disorder is probably transmitted as a Mendelian recessive trait. It is associated with hematologic and renal metabolic disturbances, including osteomalacia, pseudofractures, hypophosphatemia, renal glycosuria, and ameno-aciduria.

There may be hypoplasia of the bone marrow, anemia, leukopenia, thrombocytopenia, and ecchymosis or hemorrhage may occur in the mucous membrane.

Alterations in the blood chemistry consist of increased renal secretion of amino-acids, increased renal phosphate clearance with hyperphosphaturia, renal glycosuria and high urinary ammonia.

The chronic organic acidosis which results is thought to be from an inborn error of protein metabolism with an associated abnormal function of the proximal convoluted renal tubules and a failure to reabsorb glucose, phosphate, amino-acids, bicarbonates, potassium and uric acids.

The treatment consists of measures designed to correct the electrolyte imbalance, the administration of large doses of vitamin D, high intake of calcium and phosphorus, by the administration of alkalinizing mixtures of potassium chloride, sodium citrate and citric acid.

Cardiac Muscle

the Ultrastructure

EARL B. SCOTT, Ph.D.*
Vermillion, South Dakota

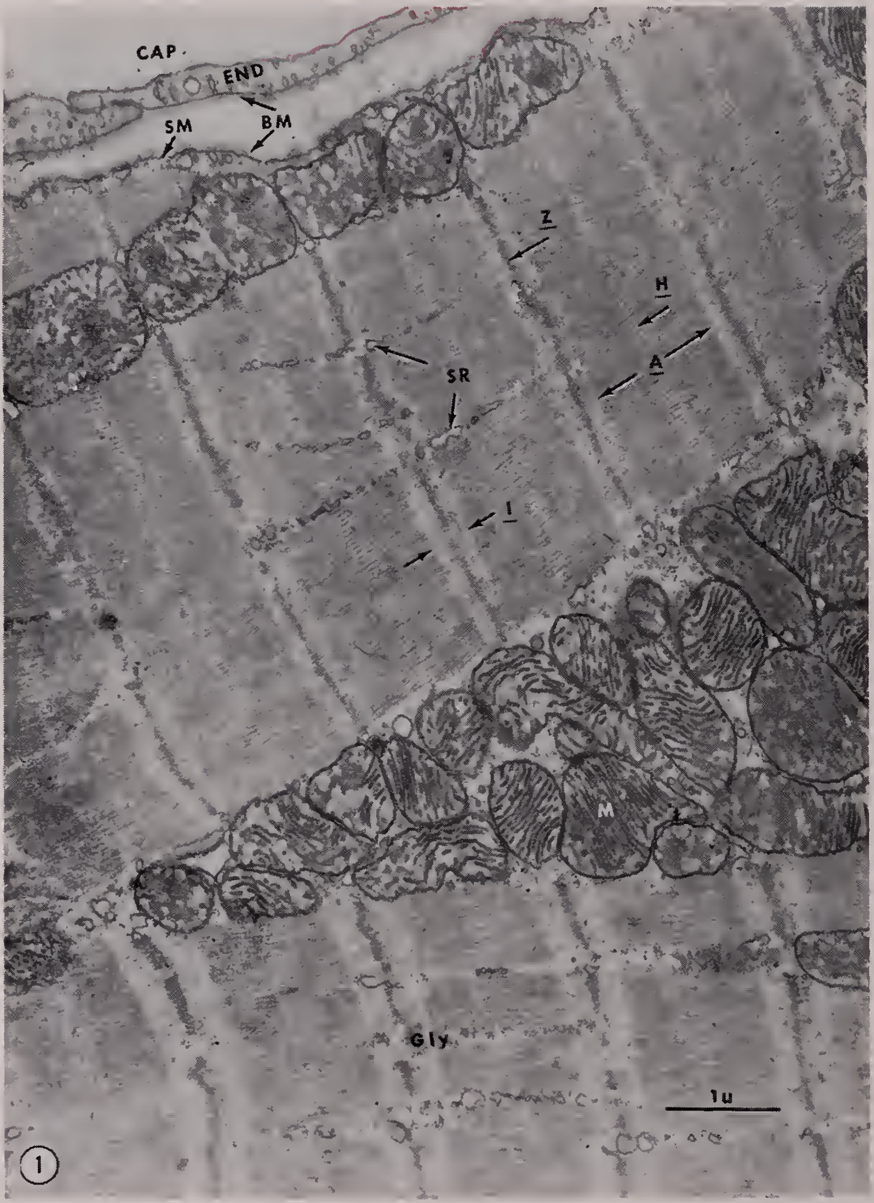

Fig. 1 — Electron micrograph of a longitudinal section of rat cardiac muscle. Lead citrate stain, X20,000. *CAP*, capillary; *END*, endothelium; *SM*, sarcolemma; *BM*, basement membrane; *SR*, sarcoplasmic reticulum; *GLY*, glycogen; *M*, mitochondria; *A*, A-band; *I*, I-band; *H*, H-band; *Z*, Z-line.

STUDIES OF THE ultrastructure of cardiac muscle in man, the dog and the rat have shown that, in general, the basic organization and morphology are similar to those of skeletal muscle.[1,2] Variations in structure from that of skeletal muscle, other than the presence of intercalated discs and branching fibers, are related to the fact that cardiac muscle fibers must contract frequently and simultaneously, with but short recovery periods.

Myofibrillae

In ultrathin longitudinal section (Figure 1) the fibers are seen to be composed of closely packed myofibrillae which are cross-banded in register. In electron micrographs, the anisotropic A-bands are dark, having a narrow, light zone, the H-band, at the mid-region. Adjacent to the A-band is a light isotropic zone, referred to as the I-band, each of which is transected by a dark Z-line. A sarcomere is described as the portion of a myofibril which is included between two successive Z-lines. In studies of the ultrastructure of skeletal muscle, it has been shown that the banding (anisotropic and isotropic areas) results from longitudinally oriented, interdigitating thick and thin filaments.[3-5] The thick filaments, averaging 100 Å in diameter, are located in the center of the sarcomere and are composed of myosin. In relaxed muscle, these filaments traverse the A-band and the H-band. The thin filaments are composed of actin, averaging 50 Å in diameter. They originate at the Z-line, traverse the I-band extending through the A-band just to the H-band. In skeletal muscle, cross-bridges between the actin and myosin filaments in the A-band have been described,[3] but these have not been particularly evident in cardiac muscle.

Filaments

In transverse sections, under high magnification, two types of filaments can be observed, and the arrangement and pattern of the filaments in different areas of the sarcomere are discernible (Figure 2). A section passing through an A-band shows the hexagonal arrangement of the thick myosin filaments, between which the orderly pattern of the less dense, thin actin filaments are located (Figure 2, encircled). A section through the H-band reveals only thick myosin filaments in orderly arrangement; a section through an I-band shows only thin actin filaments in a less orderly pattern (Figure 2).

The sarcolemma is double-layered, characteristic of plasma membrane, and is invested with a basement membrane. Numerous micropinocytotic vesicles are usually present. The cytoplasm of the fibrillae is homogeneous and contains, between fibrils, numerous, randomly distributed, electron-dense granules which have been interpreted as being composed of glycogen (Figure 1).

Heart muscle contains a complex membranous vesicular system investing the myofibrillae. This system, termed the "sarcoplasmic reticulum,"[6] is located between the myofibrillae and is composed of a system of tubules running parallel to, and transversely around them. At intervals, usually at the Z-line and the H-bands, the tubules coalesce into sacs forming winding transverse channels. An additional separate transverse tubule system, smaller in diameter than the sarcoplasmic reticulum, is also present at the Z-line. This separate system has been termed the "T-system." Together, the systems of tubules, i.e., the organization of the sarcoplasmic reticulum and the T-system, are referred to as the "triad" and are considered to be an ideal means for rapid communication and distribution of the action potentials necessary for excitation and contraction.

The mitochondrial content of cardiac muscle is extremely high as compared to skeletal muscle. These organelles are located beneath the sarcolemma and between the myofibrillae. They have no particular relationship to any region or portion of the fibrils or to the tubule system. Structurally, they are similar to mitochondria in other cells, being bounded by a double membrane, the inner layer of

which is transversely infolded to form cristae. Frequently the cristae are arranged spirally. The large number of mitochondria in heart muscle is a reflection of the high metabolic demands necessary for the continuous activity of this tissue.

Intercalated Discs

The intercalated discs, so characteristic of cardiac muscle, have been shown to consist of two specialized cytomembrane interfaces of adjacent muscle cells in the position of the Z-band.[7] The interfaces of the intercalated disc are separated along their entire winding length by a variable space, with no continuity of fibrils across this intercellular gap. Some portions appear as two apposed cell membranes without unusual differentiation (Figure 3, star), but specialized modifications are commonly present. Scattered irregularly along the disc are structural alterations resembling the form of desmosomes,* having cytomembranes of increased density and dense material in the adjacent cytoplasm (Figure 3, triangle). Another type of modification of the interface also occurs. This

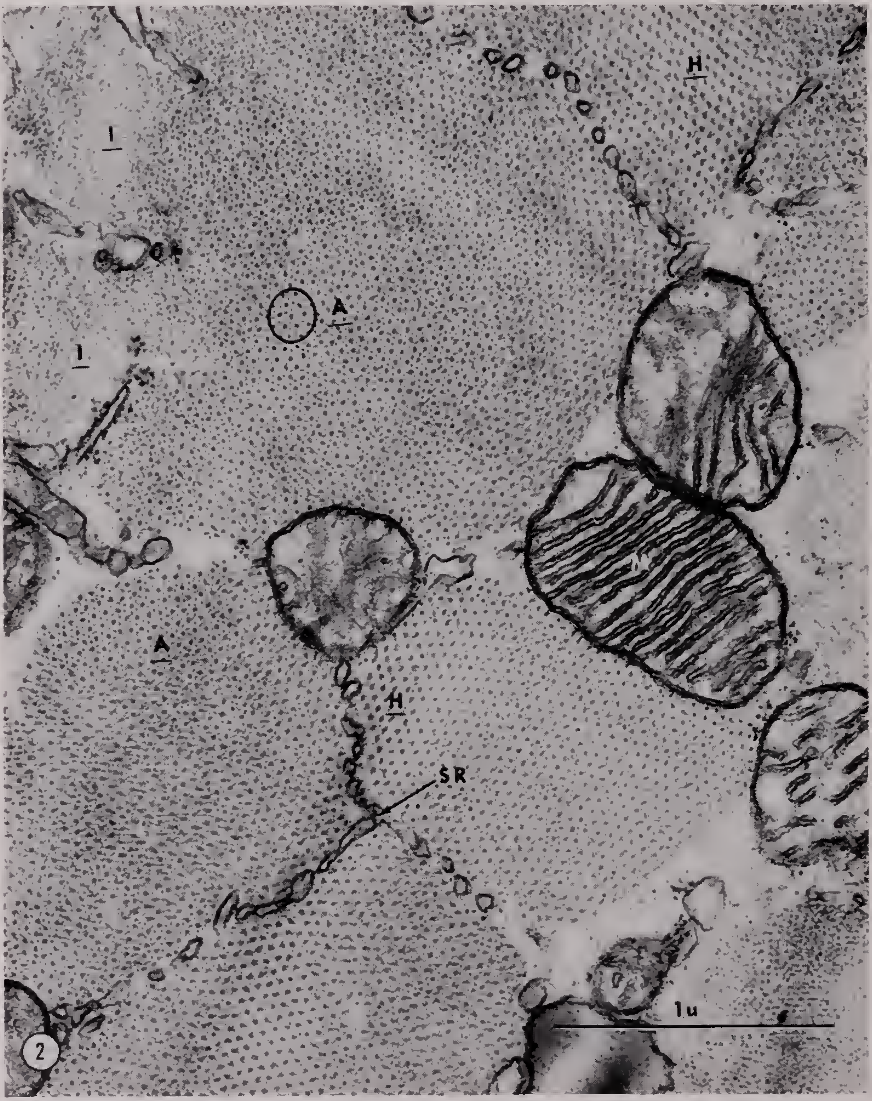

Fig. 2 — Electron micrograph of a transverse section of rat cardiac muscle. Lead citrate stain, X51,000. *CIRCLE*, hexagonal arrangement of myosin fibrils in A-band; *SR*, sarcoplasmic reticulum; *M*, mitochondria; *A*, *I*, *H* refer to sectioning through respective bands.

form appears as a very dense area of the cytomembrane, but without dense material in the adjacent cytoplasm and with a reduction in the width of the intercellular space, having the interfaces in regular close apposition, about 100 Å (Figure 3, spot).

Heart Diagnostics in Ancient Egypt

The Scribe of the ancient Egyptian Papyrus dealing with medicine was evidently cognizant of the physiological-emotional reactions of the human heart. He appears to have been sure of himself; neither incertitude nor inhibition is detectable in his naive and rather touching exposition:

> When Anger arises in his Heart, behold it is a seething-up of the parts of the Intestine and the Liver. His Ear is on the alert, his vessels fall after their rising heat has dissolved everything.
>
> When the Heart is sad, behold it is the moroseness of the Heart, or the vessels of the Heart are closed up in so far as they are not recognizable under thy hand. They grow full of Air and Water.
>
> When the Heart feels an aversion, behold it is the Bitterness of the Heart because of Inflammation in the Anus. Thou findest it big and something forms itself in his Abdomen as in his Eye.
>
> When his Heart spreads out, behold the vessels of the Heart are with excrement.
>
> When the Heart is sick, behold there is an Oppression of the Heart, or it is an Overflow of Blood which arises in the Heart. It falls down and approaches his diaphragm, while his Heart feels an aversion.
>
> When his Heart is in its right place the Fat of the Heart is on the left side. It neither rises upwards nor falls downwards. It remains soundly in its place.
>
> When his Heart trembles and there is much fat under his Left breast, behold it is his Heart which causes a little of the sinking because his disease is spreading.
>
> When dryness befalls his Heart, behold it is the dryness of Fire that befalls it. He sighs often and his Heart is eaten up with anger; this is because his Heart is full of Blood, which in turn is due to drinking Warm Water and eating Bad Food.
>
> When his Heart is afflicted and has tasted sadness, behold his Heart is closed in and darkness is in his body because of anger which is eating up his Heart.
>
> When it is Fate that he shall go Up-on-High, behold it is his Heart which determines that he shall go Up-on-High.*

Astrology & Medicine

The planets Jupiter and Venus are benefics unless so aspected that their otherwise favorable influence is voided. Strongly afflicted, Jupiter disposes to circulatory disorders, pleurisy, diabetes, and obesity; Venus to throat affections, lymphatic ailments, and venereal diseases.

During October Jupiter is morning star and Venus evening star.

Electrolyte Alterations in Cardiac Disorders*

EDWIN H. SHAW, JR., Ph.D.**
Vermillion, South Dakota

TABLE I
Distribution of Body Fluids

	% of body weight	liters per 70 kg. man
Extracellular	20	14
Blood Plasma	5	3.5
Interstitial Fluid	15	10.5
Extracellular	50	35

THE HUMAN BODY consists of some 70% water, which is distributed in the several compartments as indicated in Table 1.

Body-Water Balance

The level of body fluids is regulated quite closely by the balance between fluid intake (actual fluid, fluid content of solid foods and metabolic water produced in the combustion of foodstuffs) and fluid loss (evaporation from the lungs or skin and renal or fecal excretion). Ordinarily, *excess fluid intake* leads to a decrease in osmotic pressure of the plasma and increased renal flow with production of a dilute urine. *Decreased fluid intake* or excessive extrarenal fluid loss leads to dehydration, decrease in salivary secretion, drying of the pharyngeal mucosa and thirst. Secretion of the antidiuretic hormone by the pituitary contributes to the conservation of water in this condition. Ordinarily, the satisfying of thirst controls the total body fluid.

Influencing Factors

In addition to the role of the kidney and pituitary body in regulating total fluid volume, the renal conservation of electrolytes is mediated by the adrenal hormones, particularly aldosterone, which controls the tubular reabsorption of sodium in exchange for excreted potassium and hydrogen ion. The net result of osmotic and electrolyte regulation is a rather accurately controlled homeostasis with the stable milieu interne of Claude Bernard reflecting in its composition the probable analysis of sea water at the time when the early vertebrates moved from the marine to the fresh-water environment.

The constancy of distribution of fluids between the several compartments listed in Table 1 depends on the factors controlling the secretion of lymph and its reabsorption.

---

**Department of Biochemistry, University of South Dakota Medical School.

Fundamentally, secretion of lymph and its reabsorption depend on the colloidal osmotic pressure of plasma (oncotic pressure) in relation to the hydrostatic pressure of the circulating blood, as indicated by the following equation relating to the capillaries:

(secretory pressure) = (blood pressure) — (oncotic pressure)

To demonstrate the relationship diagrammatically, Figure 1 illustrates the equilibrium in a tissue capillary, the numerical figures being somewhat arbitrary.

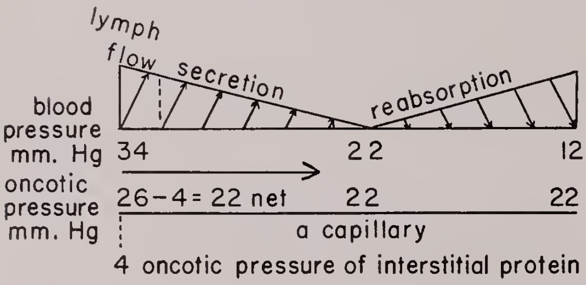

Fig. 1 — Normal Secretion of Lymph.

Renal Edema

In the case of renal edema, in the nephrotic syndrome, the loss of plasma albumin lowers the colloidal osmotic pressure of plasma, shifting the point of no secretion to the right and increasing the excess of secretion beyond what can be removed by the normal lymph flow, the excess remaining in the tissue spaces as edema. In congestive heart failure, accumulation of fluid in the capillaries leads to both dilation and ischemia of the tissue capillaries with increased permeability for protein. With increased protein in the tissue spaces, the net colloidal osmotic pressure is reduced. Due to congestion, blood pressure in the capillaries is increased. Both these factors increase the secretory pressure, with resulting edema as indicated in Figure 2, the numerical figures being arbitrary.

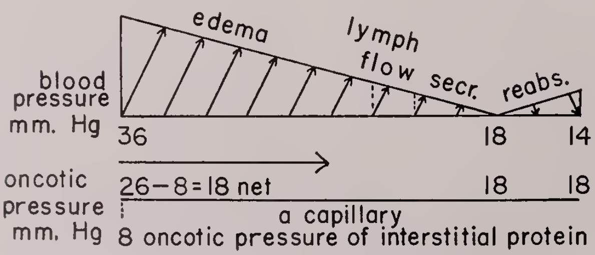

Fig. 2 — Edema in Congestive Heart Failure.

Backward Failure

In a recent symposium, Streeten[1] has reviewed the theories of backward and forward failure as they apply to congestive heart failure. Hoffman[2] has also presented the rationale of these two concepts, which are not mutually exclusive.

According to the backward-failure concept, the stretched myocardial fibers no longer allow complete emptying of the heart on systole, so that an excess of blood accumulates behind the heart, increasing the venous pressure back to the venous end of the capillaries, leading to increased transudation of lymph as indicated in Figure 2. The accumulation of fluid in the tissue spaces, which can take place without the supplying of additional salt, leads to a hypovolemia in the intravascular fluids and an increase in fluid intake, diluting the plasma and stimulating secretion of vasopressin by the action of osmoreceptors in the diencephalon.

The intermediation of "volume"[3] or "stretch" receptors, whose localization is not definite but has been variously assigned to the hypothalamus, aorta, carotid, atria, the great veins, the central arteries or to the kidney itself, may, by a mechanism which is independent of the hypophysis, cause an increase in aldosterone, which tends to increase the retention of sodium, favoring the retention of the edema, which develops insidiously and rapidly with a hyponatremic plasma. Because of the intravascular hypovolemia and hyponatremia, the delivery of the edema is difficult, requiring use of the mercurial diuretics.

Forward Failure

The forward-failure concept is based on a diminution of cardiac output, so that the pressure and volume of blood in the great arteries are low, with the result that the "volume" or "stretch" receptors postulated above are presumed to increase the production of aldosterone, with the same results as occur in the backward-failure concept, but with the additional result of a decrease in renal plasma flow and glomerular filtration. The tubular activity would still be near normal, so that a large reabsorption of sodium chloride and water would be expected to produce an eventual engorgement of the capillary and venous circulation with simultaneous edema. In this concept there is the additional factor of a greater degree of competence in the right heart than in the left (which is usually the site of failure), so that more blood is delivered to the smaller (5% of vascular volume[4]) pulmonary bed than to the larger (55% of vascular volume) systemic bed, with resultant pulmonary congestion and dyspnea with rapid shallow breathing.

Left Ventricular Failure

Left ventricular failure results in decreased blood flow through nearly all the regions of the body with a correspondingly greater extraction of oxygen from the slowly moving blood and a lowering of the venous oxygen reserve. Because of restricted blood flow through skeletal muscle, fatigue and weakness may be symptoms.[5]

Right Ventricular Failure

Conversely, when there is right ventricular failure, general systemic venous congestion and peripheral edema are prominent, with obvious engorgement of the liver, spleen, splanchnic bed and skin. Elevated venous pressure with distention of the veins, peripheral edema and ascites are obvious symptoms.

Treatment Rationale

It has been pointed out by Maxwell and Kleeman[6] that the increased vasopressin and aldosterone in congestive heart failure not only promote reabsorption of water and sodium chloride, but that aldosterone promotes the tubular loss of hydrogen ion and potassium in exchange for the sodium retained, significantly reducing the cellular potassium reserves. Increased vasopressin results in water conservation with production of hyponatremic enema,* in which the serum potassium may be either high or low. The obvious rationale of treatment is the early promotion of diuresis by mercurial diuretics, digitalization, and the eventual use of a low-salt diet with the chlorothiazide type of diuretics. In view of the fact that there is frequently depletion of potassium and chloride, it is usually necessary to administer oral potassium chloride. During the period of early treatment, while edema is being delivered and digitalization accomplished, serum electrolyte analysis, particularly sodium and potassium, is a useful adjunct to rational treatment.

With the recent emphasis on the role of increased vasopressin (antidiuretic hormone) on the retention of water, and of aldosterone on the reabsorption of sodium at the expense of lost potassium, the hyponatremic edema of chronic congestive heart failure has been visualized by Takasu et al.[7] in terms of the osmolar clearance and water clearance[8] under conditions of water loading and water deprivation. The osmolar clearance is the milliosmols excreted per minute, the ratio of osmolarity of urine to osmolarity of plasma multiplied by the ml. of urine excreted per minute.

$$C_{osm} = \frac{U_{osm}}{P_{osm}}. V$$

The free-water clearance is obtained by subtracting the osmolar clearance from the volume of urine per minute. The result may be positive for urines more dilute than blood plasma or negative for urines more concentrated than blood plasma.

$$C_{H_2O} = V - C_{osm}$$

The free-water clearance in congestive heart failure is less responsive to a water load, remaining lower than normal responses, and the osmolar clearance does not rise to its normal height during a subsequent fluid restriction period. Takasu et al.[7] recognize several groups in which the hyponatremia of chronic congestive heart failure is due to:

1. Low setting of the osmoreceptors controlling secretion of the antidiuretic hormone. These patients excreted large amounts of free water on water loading but remained hyponatremic, although the urine osmolarity increased during the ensuing water-deprivation period.
2. Glomerulotubular imbalance with lowered glomerular filtration and normal

---

*See Test Your Word Score Page 1333.

tubular secretion. These patients maintained a relatively low and constant osmolar clearance and water clearance, unaffected by the intake or deprivation of water. A portion of these showed delayed water clearance, the response occurring during the nocturnal fluid restriction period.

3. A combination of glomerulotubular imbalance and a low setting of the osmoreceptors. These patients excreted the water-load fluid during the night rather than at the time when water was administered.

Summary

The regulation of water and sodium content of blood plasma are under the regulatory control of vasopressin (antidiuretic hormone) and aldosterone respectively. In congestive heart failure, hyponatremic edema is a regular finding, induced by an increased secretion of vasopressin (antidiuretic hormone) under the influence of osmoreceptors in the diencephalon, which retains water, and an increase in aldosterone under the influence of as yet vaguely understood "volume" or "stretch" receptors. The hyponatremic edema requires mercurial diuretics to start delivery of the edema, followed by digitalization and cholorothiazide type diuretics for control.

Progress

"I've tried all the medical faculty: they can diagnose beautifully, they have the whole of your disease at their finger-tips, but they've no idea how to cure you. There was an enthusiastic little student here, 'You may die,' said he, 'but you'll know perfectly what disease you are dying of!' And then what a way they have of sending people to specialists. 'We only diagnose,' they say, 'but go to such-and-such a specialist, he'll cure you.' The old doctor who used to cure all sorts of disease has completely disappeared, I assure you, now there are only specialists and they all advertise in the newspapers. If anything is wrong with your nose, they send you to Paris: there, they say, is a European specialist who cures noses. If you go to Paris, he'll look at your nose; I can only cure your right nostril, he'll tell you, for I don't cure the left nostril, that's not my specialty, but go to Vienna, there there's a specialist who will cure your left nostril. What are you going to do? I fell back on popular remedies."

The Chemistry
of
Congestive Heart Failure*

J. D. WELTY, Ph.D.**
Vermillion, South Dakota

NORMAL FUNCTION of the heart depends upon the rhythmic, coordinated, sequential contraction of its parts. Failure of rhythmic excitation, abnormalities of excitability, or loss of contractility give rise to impaired function.

Types of Congestive Heart Failure

It is an important generalization that congestive heart failure occurs when the load imposed upon the heart exceeds the capacity of the heart for work. Olson and Schwartz[1] have suggested that congestive heart failure can be divided biochemically and hemodynamically into two forms: high-output metabolic failure and low-output nonmetabolic failure.

High-Output Metabolic Failure

In high-output metabolic failure, factors such as anemia, thyrotoxicosis, beri beri, etc. interfere with energy production in the cardiac muscle and are responsible for the ultimate failure of the myocardium. In severe anemia or anoxia the oxidative enzymes of the Krebs cycle and electron transport do not function and deteriorate rapidly following periods of relative anoxia. These changes are associated with fragmentation of the normal ultra-structure of the myocardial sarcosomes. Studies have shown that the decline in work capacity associated with anoxia is proportional to the decline in phosphocreatine content and later to a fall in adenosinetriphosphate (ATP) concentration. Myocardial failure resulting from hormonal imbalances such as thyrotoxicosis is also due to a defect in free energy production. In this case the oxygen consumption is highly elevated, but there is over-all low cardiac efficiency. The myocardial stores of ATP and phosphocreatine are exhausted, a condition related to the blockage of oxidative phosphorylation by thyroxin. Failures such as those seen in beri beri are related to a lack of the coenzyme thiamine, resulting in a depletion of cocarboxylase. This coenzyme is concerned with the conversion of pyruvate to acetyl coenzyme A; thus the oxidation of carbohydrates cannot proceed to completion — with resultant loss of energy.

Low-Output Nonmetabolic Failure

Energy production appears to be preserved in low-output nonmetabolic failure. According to Wollenberger[2] failure occurs because of an inability of the myocardium to utilize the energy produced. The metabolic behavior of the failing heart in dogs subjected to cardiac valvular surgery (producing chronic low-output congestive heart failure) revealed

**Assistant Professor of Physiology, Department of Physiology and Pharmacology, University of South Dakota School of Medicine.

that in comparison to normal dogs, the cardiac output was decreased, but coronary blood flow and myocardial oxygen consumption were normal. Rossi and Dianzani[3] could demonstrate no defect in oxidative phosphorylation and indeed found the level of high-energy phosphate compounds to be normal in low-output failure. Studies using the dog heart-lung preparation, open and closed-chest dog experiments, and human subjects, have shown that glycolytic enzymes of the cytoplasm, the dehydrogenases, and the electron transport chain of the sarcosomes function normally.

Influence of Oxygen

It has been suggested in the past that anoxia within the hypertrophied cardiac muscle was responsible for the failure of contractility. Experiments using cardiac catherization demonstrated no decrease in coronary blood flow, oxygen extraction capacity, or substrate utilization in human subjects with hypertrophy and congestive heart failure. Indeed Dock[4] has pointed out that the coronary blood flow in cardiac hypertrophy without coronary disease is more than adequate to provide oxygen in excess of the requirements. Bing et al.[5] have also reported that the oxygen consumption of patients with failure of valvular origin was normal. In examining the protein content of hypertrophied rat hearts, Sobel and Cohen[6] have demonstrated an increase in the myoglobin and mitochondrial fractions. These apparent increases indicate a further expansion of the oxygen-transporting and oxygen-utilizing systems.

Stress Factor

In a search for the factor or factors responsible for the deficient energy utilization in congestive heart failure, attention has been directed toward the energy-utilizing component of muscle contraction, the actomyosin system.

Early in the development of congestive heart failure an excessive stress is imposed upon the heart, primarily in the form of increased distention. Holland and Klein[7] have suggested that this stress could lead to failure by (1) development of a decrease of excitation-contraction coupling associated with the endoplasmic reticular system; (2) loss of essential electrolytes such as potassium, calcium or sodium; or (3) development of abnormal contractile proteins. Recent findings in the literature suggest that the latter may be the most probable cause. Studies by numerous authors have served to advance our understanding of the mechanism of energy utilization in muscle contraction. Attention has been directed to the three proteins, myosin, actin and tropomyosin, which, together with calcium, function as the primary mediators of muscle contraction and the energy-utilizing system.

Abnormal Actomyosin

Mallov and Robb[8] were the first to report the possibility of the presence of abnormal actomyosin in congestive heart failure. In 1955 Benson[9] reported that dogs in myocardial failure, produced by tricuspid insufficiency and pulmonary stenosis, had a decreased concentration of actomyosin in the heart. In addition, these results suggested that this actomyosin was altered and present in a partially dissociated state. Olson[10] and his group characterized the myosin from similarly produced failing hearts and demonstrated that it had a higher molecular weight (695,000) than myosin from normal hearts (226,000). Extended observations on failing heart myosin by these authors[11,12] demonstrated abnormal patterns in ultra centrifugation and electrophoresis. Small changes in the myosin molecule could have profound changes in its function. Ellenbogen et al.[13] have reported an increase in amide nitrogen of myosin from failing hearts. Such a change could have a gross effect on the functional capacity of myosin. Increase in amide nitrogen implies a decrease in total negative charge, which could affect the hydrogen bonding that would appear to be necessary for the three-stranded helix of myosin proposed by Keilley and Harrington.[14] These authors further suggest that one amino acid, proline, required in the proper sequence, is responsible for the folding of the molecule. If this amino acid were not present in the proper position, an abnormal myosin molecule would result. Since the time when Engelhardt and Lyumbimova[15] reported that myosin possessed adenosinetriphosphatase (ATPase) activity, much concern has been given to this reaction as the intermediate mechanism of energy utilization. While studies on ATPase activity of myosin in heart failure have not produced consistent results, numerous authors have reported reductions in ATPase activity in failing human hearts. This could mean some basic alteration in the myosin molecule or in that restricted site on the myosin molecule concerned with ATPase activity. These and other studies point to the possibility of an abnormal myosin which cannot form a proper complex with actin.

Other authors, reviewed by Bing and Kako,[16] have been concerned with the actomyosin system of human failing hearts. Changes in the myosin molecule were observed to take place during failure which were similar to those reported for the "produced failure" in dogs. In addition, work on glycerol-extracted muscle-fiber bundles from failing human hearts reported that failing human hearts develop less tension and exhibit less contractility than similar fiber bundles prepared from normal hearts. Again it is possible to see how small subtle changes on the myosin molecule could affect gross changes in contractility. According to Weber's hypothesis[17] certain reactive groups suggested as sulfhydryl, phenolic hydroxyl, and alcoholic hydroxyl groups located along the myosin molecule in a specific sequence allow for interaction with a phosphorylated site on the action molecule, with resultant tension development and shortening. It is possible that substitution of an improper amino-acid sequence along this reactive group portion of the myosin chain could affect shortening, but may or may not affect the myosin ATPase activity.

Glycoside-Myosin Complex

It is interesting to note that the digitalis glycosides are of little use in the type of heart failure due to lack of energy production and appear to be effective only in case of deficient energy utilization. Brown, Stafford and Wright[18] have shown that there are three centers in a "cardiac" aglycone molecule which must be present for cardiac activity. These centers are (1) a hydroxyl group at carbon-3; (2) a 14 β-hydroxyl; and (3) an unsaturated lactone ring. Waser,[19] in summarizing his investigations on the interaction between digitalis and contractile proteins, found that a glycoside-myosin complex is formed. This author[20] further found in autoradiographs of muscle bundles, perfused via a small artery with tritiated digitoxin, radioactivity on the outside of the membranes as well as inside the muscle cells. This tends to confirm the dual role widely suggested for the cardiac glycosides. The rationale for use of cardiac glycosides on isolated systems is due to the effect that digitalis has in strengthening the intact failing heart; thus, any action on the pure protein could point to the defect in the failing heart. It is interesting to note the chemical similarity between the active cardiac glycoside centers and the actin-binding sites on the myosin molecule. The formation of a myosin-glycoside complex could be associated with the actin-binding sites on the myosin molecule, thus allowing for the proper interaction with actin.

Compensatory Hyperfunction

When a decompensated heart is subjected to prolonged stress, compensatory hyperfunction (Katz[21]) occurs. Associated with this hyperfunction is an increase in cardiac ribonucleic acid (RNA),[22,23] an increase in myocardial transaminase,[24] and a tremendous increase in the rate of protein synthesis.[25] It is interesting to note that this increased rate of protein synthesis does not occur in hypophysectomized rats.[26] This can be explained by the work of Korner,[27] who suggested that the growth hormone, secreted by the anterior pituitary gland, is required for the combination of messenger RNA and the ribosomal RNA template.

Thus we can see that certain hormones, which appear in excessive quantities in the congestive heart-failure syndrome, can influence other cellular functions than the energy-producing systems. It has been shown that during the initial phase of increased protein synthesis an abnormal contractile protein fraction (actomyosin fraction) can be demonstrated.[6]

Meerson[28] has suggested that cardiac insufficiency may result from a depression of the normal replacement of the contractile elements. This may be analogous to the theory of Comfort,[29] who suggests that every stress imposed upon a structure results in a "wearing out" of that structure. While this may or may not be the case, this stress could affect the protein-synthesis mechanism resulting in improper structures.

In view of the evidence cited for an abnormal contractile protein it would appear that the primary causative factor in myocardial failure is a biochemical defect within the heart which may result in an improper amino-acid incorporation into the contractile proteins.

Comments

At the present time studies are under way in this laboratory to elucidate the amino-acid composition of failing-heart contractile proteins. Using the method of Benson,[9] which we have slightly modified, we have been able to produce congestive heart failure in dogs at much reduced mortality rates. The amino-acid composition of failing-heart myosin, as well as the other contractile proteins, will be reported in separate papers.

The evidence suggested for an abnormal myosin molecule in failing hearts does not exclude the possibility of other abnormal contractile proteins. This possibility is also presently under investigation. The common denominator of most forms of heart failure would still appear to be the inability of the actomyosin system, which forms the myofibrils, to assimilate the energy of the phosphate bond and convert it into kinetic energy of contraction.

Response of the Myocardium to Drugs

JOSEPH N. SPENCER, Ph.D.*
Vermillion, South Dakota

ALMOST ANY DRUG administered for its systemic action may produce some alterations in myocardial function. Commonly these effects are the result of a compensatory reflex action, not of a direct action on the cardiac muscle. This discussion will be limited to a few of the drugs acting directly on the myocardium.

Cardiac Glycosides

These are myocardial stimulants. They are natural products, those in common clinical use being derived from Digitalis purpura or lanata. The use of glycosides from these particular plants is based more on custom than any actual superiority over glycosides from other natural sources. All cardiac glycosides, regardless of their sources, have a similar pharmacological action.[1]

Chemically, a glycoside consists of an aglycone and a sugar.[2] The aglycone is the active portion of the glycoside. The sugar is attached through a glycosidic linkage to the aglycone; it facilitates tissue penetration of the aglycone and markedly potentiates the latter's cardiotonic action.

Mode of Action

On absorption the cardiac glycosides appear to be distributed throughout the body, at least a portion being bound in the myofibrils.[3] Studies on muscle contraction have established that the myofibril, to contract, requires not only adenosine triphosphate (ATP) but calcium as well.[4] Within limits, the force of cardiac myofibril contraction appears to vary in direct proportion to the level of intracellular calcium.[5] The cardiac glycosides stimulate the rate of flow of calcium into the myofibril.[6] This increase in myofibril calcium may account for the entire cardiotonic action of the glycosides. However, in addition to their effect on calcium, the glycosides tend to favor the outflow of potassium[1,7] and to inhibit sodium-potassium-activated adenosine triphosphatase (Na^+ +

---

*Department of Physiology and Pharmacology, University of South Dakota School of Medicine.

K^+ − ATPase).[8] The alterations in potassium flux are probably secondary to those of calcium, but the significance of the action on $Na^+ + K^+$ − ATPase is not clear. It may be a manifestation of glycoside toxicity.[9]

Pharmacologic Actions of Cardiac Glycosides

Cardiac Muscle

The cardiac glycosides have no beneficial action on the normal heart muscle; their typical action is seen only on the decompensated heart. The refractory period of cardiac muscle is decreased and the force of ventricular contraction increased. Heart size is reduced toward normal, cardiac output increased, and venous pressure and edema reduced. The over-all effect is an improvement in cardiac efficiency.

Conduction

The refractory period of the AV node and Bundle of His is lengthened. This, along with the general improvement in the circulation, leads to a slowing of the ventricular rate. Slowing occurs despite an actual reduction in the refractory period of the cardiac muscle and an increase in force of ventricular contraction. This action of the glycosides on conduction may be utilized to advantage in auricular flutter and fibrillation. In the former condition, the flutter may be converted to fibrillation, which on withdrawal of the glycoside, may revert to normal rhythm. In addition, in both auricular flutter and fibrillation, the glycosides tend to protect the ventricle from excessive auricular stimulation.

Vagal Action

The cardiac influence of the vagus is increased by the glycosides. In part, this may be due to central vagal stimulation and in part to the improvement in circulation (decreased influence of the Bainbridge Reflex). Also, it is possible that the glycosides reduce the threshold of the SA node to vagal action. These vagal actions contribute to the slowing of the ventricular rate and have a practical application in the control of auricular tachycardia.

Other Action of the Cardiac Glycosides

These are either of minor therapeutic importance or actual manifestations of toxicity.

a. Diuretic Action: The glycosides have some direct diuretic activity and will reduce tubular reabsorption of salt and water. However, this action is not of sufficient magnitude to be of clinical importance. In the presence of cardiac edema, the glycosides produce a marked diuresis, but this is secondary to the general improvement in the circulation.

b. Stimulation of Cardiac Automaticity: This is actually a manifestation of glycoside toxicity. With increased glycoside action, the muscular effects predominate. Myocardial refractory period becomes progressively shorter, and eventually arrhythmias result. Auricular disturbances, premature ventricular contractions, coupling and/or ventricular tachycardia may occur. Although these are manifestations of toxicity, with care this ability of the glycosides to stimulate automaticity may be utilized to stimulate ventricular rhythm in heart block.

TABLE I
Dose and Characteristics of Some Glycoside Preparations

		%	Dose in Mg.				Approximate
Preparation	Route	Absorbed	Initial	Maintenance	Onset of Action	Maximal Effect	Duration of Action
Digitalis USP	PO	10–20	1200	100–200	6 hr.	30 hr.	18–30 days
Digitoxin USP	PO	100	1–1.5	0.05–0.2	2 hr.	12 hr.	20 days
(Crystodigen, etc.)	IV	—	1–1.5	0.05–0.2	30 min.	8 hr.	20 days
Digoxin USP	PO	50	2–4	0.2–0.75	2 hr.	8 hr.	4–7 days
(Lanoxin)	IV	—	0.75–1	0.2–0.75	5 min.	5 hr.	4–7 days
Lanatoside C, NF	PO	10–20	5–10	0.5–2	2 hr.	6–8 hr.	2–3 days
(Cedilanid)	IV	—	1.2–1.6	0.5–1	8 min.	3 hr.	2–3 days
Ouabain USP	PO	unreliable	—	—	—	—	—
	IV	—	0.3–0.5	—	5 min.	90 min.	24 hr.

c. Central Nervous System: This may be stimulated or depressed; the actions are purely manifestations of toxicity. In the early stages neuralgia, paresthesia and malaise predominate; later, anorexia, emesis and visual disturbances are common.

Dosage and Toxicity

The principles of dosage established by Withering in 1785 still apply.[1] "Let it be continued until it either acts on the kidney, the stomach, the pulse or the bowel; let it be stopped at the first appearance of any of these effects." Table 1 lists a few of the common preparations, their usual initial dose and an estimate of their onset and duration of action.

It is of interest that the duration of action of any one preparation appears to be directly related to its ability to be eliminated without metabolic degradation. Digitoxin, with a duration of action of approximately twenty days, is almost completely metabolized, only traces being excreted unchanged.[2] Ouabain, on the other hand, which acts for relatively few hours, appears to be eliminated unchanged in its entirety.[10]

The cardiac glycosides are potent, cumulative drugs. It is difficult for them to be administered without some manifestation of toxicity. Commonly, reduction in dose or drug withdrawal will suffice.[1] However, in cases of severe intoxication where there may be disturbing cardiac arrhythmias, specific treatment may be indicated. The cardiac depressants, quinidine and Pronestyl, are not overly effective in antagonizing the glycoside-induced arrhythmias.[1] Potassium salts have been employed on the assumption that a reciprocal relationship exists between the concentration of myocardial potassium and glycoside toxicity.[1,2] Restoration of normal cardiac rhythm has been reported, but few of the cases have been supported by laboratory data.[1] On the other hand, Gubner and Kallman,[11] in studies on patients with acute poisoning from cardiac glycosides, observed that the intravenous administration of Disodium Versenate, a calcium chelating agent, produced an almost immediate restoration of a normal sinus rhythm.

Sympathomimetic Amines

All sympathomimetic amines will stimulate the myocardium, but due to their marked effects on other systems, only a few find use as myocardial stimulants.[1] Isoprel is the most potent and probably the most useful, but epinephrine, neosynepherine, Wyamine, Aramine and similar agents are probably equally effective. Their action is comparable to that of sympathetic stimulation. The force of ventricular contraction is increased. The myocardial refractory period as well as that of the SA node, the AV node and the Bundle of His is decreased. There is also an increase in cardiac automaticity. The primary disadvantage of these drugs is their fleeting action, a few minutes at the most.

The sympathomimetic amines have their greatest application in the stimulation of ventricular rhythm in heart block or delayed conduction. Also, they may be useful in ventricular asystole. Where chronic stimulation is desired, ephedrine, because of its more prolonged action and ease of administration, is the drug of choice.[1]

Myocardial Depressants

Quinidine and Pronestyl (procaine amide) are the most useful of the cardiac depressants.[1,2] They appear to be identical in their mode of action and are approximately equal in their clinical effectiveness and safety. They are general tissue depressants, acting through their ability to inhibit the efflux of intracellular potassium. They depress the vagus, the SA node and the AV node, and they inhibit conduction through the Bundle of His. Myocardial metabolism is decreased and repolarization is prolonged. In the usual dose, ventricular contractile force is little altered, but is decreased following large doses.

These drugs find their greatest application in those patients where depression of cardiac automaticity is indicated.[1] In the absence of increased automaticity their use may be harmful. They are most useful in the suppression of arrhythmias of auricular origin but are also of value in the control of ventricular arrhythmias. Even under ideal conditions, they are only 60% to 70% effective, although digitalization may perhaps increase the chance of success.

The drugs are relatively slowly but almost completely absorbed on oral administration. Elimination is less efficient and care must be exercised if cumulative toxic effects are to be avoided. Quinidine probably offers the greatest hazard, but procaine amide may be equally hazardous in the presence of congested heart failure or impaired renal function. The most serious effects are cinchonism* and/or vascular collapse.

The cardiac depressants are useful adjuncts in electrical countershock therapy of cardiac arrhythmias. The administration of one of these drugs for a day or two prior to electrotherapy markedly reduces the frequency of immediate relapse, and their continued use tends to prolong the duration of the reestablished rhythm.

Summary

There are a number of drugs which are capable of altering myocardial function but only a few that have a direct cardiac action.

1. The cardiac glycosides are the most useful of the direct acting myocardial stimulants. Unless there is a specific contraindication, i.e., ventricular tachycardia, their use is invariably indicated in cardiac failure.

2. Quinidine and Pronestyl are the most useful cardiac depressants. These drugs have their greatest application where depression of cardiac automaticity is indicated.

*See Test Your Word Score Page 1333.

JOHN OF MIRFIELD: he composed the BREVIARIUM BARTHOLOMEI, a medical work, probably between 1380 and 1395.

In the BREVIARIUM are some clinical tests of prognostic significance: "If the right eye of a sick man sheds tears, he will die; in the case of a woman, this applies to the left eye. The sole of a patient's right foot should be anointed with lard, which lard is then thrown to any given dog; if the dog eats it without vomiting, the patient will live, but if the dog returns it or makes no attempt to eat it, the patient will die." Mixed up with these mystic and messy investigations is much sound medicine, and even more common sense. For example, if there is any doubt as to whether a person is or is not dead: "apply lightly roasted onion to his nostrils. If he is alive, he will immediately scratch his nose."*

Glutamic–Oxalacetic Transaminase[*]

Origin
and
Fate

JERRY B. CRITZ, Ph.D.[**]
Vermillion, South Dakota

TRANSAMINATION CAN be defined in general terms as a chemical reaction in which an amino group is transferred from an amino acid to a keto acid without the intermediate appearance of ammonia.

A nonenzymatic reaction was first reported by Needham[1] in 1930 and was described in more detail in 1934 by Herbst and Engel.[2] However, true enzymatic transamination was discovered by Braunstein and Kritsman in 1937.[3] These investigators found an enzyme in pigeon breast muscle which catalyzed the transfer of the amino group from glutamic acid to pyruvic acid. Cammarata and Cohen found 22 additional amino acids that could enter into transaminase reactions.[4] The specific enzyme this paper is concerned with is glutamic-oxalacetic transaminase. The reaction catalyzed by this enzyme is described by the equation:

$$\text{Aspartic acid} + \alpha\text{-keto glutaric acid} \xrightleftharpoons{\text{glutamic-oxalacetic transaminase}} \text{oxalacetic acid} + \text{glutamic acid}$$

Evidence was presented as early as 1945 implicating pyridoxal phosphate as the coenzyme for the above reaction.[5] It is known to be the coenzyme for most transaminase systems.

Much biochemical information is now available concerning glutamic-oxalacetic transaminase. Cohen[6] in 1940 found the optimum temperature was 40°C and the optimum pH was 7.5. The research of Karmen et al.[7] suggested a range for the optimum pH of 7.0 – 8.0. The best preparations of glutamic-oxalacetic transaminase to date[8] indicate (ultracentrifuge) a molecular weight of 110,000. Research carried out on this same preparation suggested that the enzyme may be formed by two polypeptide chains with the same N-terminal amino-acid residue; alanine. Electrophoretic studies have yielded variable results, probably due to the use of progressively purer glutamic-oxalacetic transaminase preparations.[9,10] The most recent study has revealed three anionic and two cationic glutamic-oxalacetic transaminase isozymes.[11] The fractionation work of Cammarata and Cohen, already mentioned,[9] gave a yield of 0.5 gram per 1,000 grams of wet pig-heart tissue. Preliminary research has suggested that the glutamic-oxalacetic transaminase enzyme has two active sites; one for oxalacetate and aspartate and the other for ketoglutarate and glutamate.[12]

The majority of investigators agree there are probably at least two varieties of glutamic-oxalacetic transaminase, one present in high concentration and located in the mitochondria, and the other in the supernatant (soluble) fraction of the cell.[13-16] In addition, one of the above investigators has reported that the nuclear fraction also contains a high amount of glutamic-oxalacetic transaminase activity.[15] Recently an immunochemical difference has been described between the glutamic-oxalacetic transaminase from the mitochondrial and the soluble fractions of the cell.[17] The presence of glutamic-oxalacetic transaminase in the mitochondria may be of significance since this is the site of adenosine triphosphate synthesis.

Glutamic-oxalacetic transaminase is widely distributed in living organisms. It has been found in blood and many other tissues of animals, in plants and bacteria. Research carried out with tissue homogenates demonstrated that glutamic-oxalacetic transaminase was found in the following tissues of the rat in descending order of activity: heart, skeletal muscle, lung, brain, liver, spleen, prostate and testis.[18] This laboratory has confirmed these results in part; we have found rat heart to contain the highest glutamic-oxalacetic transaminase activity, followed by skeletal muscle and liver in that order.[19] Katsura and Yamamoto have confirmed the low glutamic-oxalacetic transaminase activity of endocrine tissue.[20]

Distribution of Transaminase

It is of interest that there is a further distribution of glutamic-oxalacetic transaminase within the heart. Barbieri was the first to report (1957) that the left ventricular glutamic-oxalacetic transaminase was higher than that of the right ventricle.[21] This finding was confirmed by Redetzki et al. in 1958.[22] Vacek and Sevelova in 1962 noted that experimental hypertension in rabbits (induced by ephedrine or nephrogenic hypertension) resulted in an elevated glutamic-oxalacetic transaminase content in the aorta.[23] Our laboratory has extended this observation to the heart. Blood pressure in rats was elevated by means of desoxycorticosterone acetate or by banding of the abdominal aorta. Such treatment resulted in elevated glutamic-oxalacetic transaminase in the left ventricle of the heart, while right ventricular glutamic-oxalacetic transaminase remained unchanged.[24,25] It is also of interest to note that the glutamic-oxalacetic transaminase content of the left ventricle could be elevated by a 15-minute or by a 60-minute swim.[19]

Serum-Transaminase

The fact that heart muscle contained a high concentration of glutamic-oxalacetic transaminase while very small amounts were present in serum led to the prediction that injuries to the heart could be detected and/or confirmed by a rise in serum-activity-transaminase. This was first demonstrated by LaDue et al. in 1954.[26] Their observations led to a wide variety of experiments designed to relate severity of myocardial infarction to serum-activity-transaminase levels. Since liver and brain also contained relatively large amounts of glutamic-oxalacetic transaminase, disease states involving these organs were also investigated in relation to changes in serum levels of the enzyme.

Skeletal muscle also contains a high concentration of glutamic-oxalacetic transaminase; thus open-chest methods for producing myocardial infarction have the possible added error factor of skeletal muscle injury and release of this glutamic-oxalacetic transaminase into the serum. Due to the possibility of this error, coronary embolization by use of plastic microspheres was utilized. This procedure is relatively atraumatic. Studies using this technique revealed that as little as 5-10% infarction of the heart, involving less than one gram of tissue, resulted in a significant rise in serum-activity-transaminase. Also, the magnitude of serum-activity-transaminase elevation was approximately proportional to the size of the infarct.[27] Brodell et al. have shown that more than 200 grams of cerebral tissue must be involved in an infarct before there will be a significant increase in glutamic-oxalacetic transaminase of the cerebrospinal fluid.[28] However, this laboratory has been unable to demonstrate a significant glutamic-oxalacetic transaminase contribution to the serum due to the surgical procedures attendant on ligation of one of the coronary arteries. Similar results in other laboratories have been obtained by the use of open-chest methods. This adds support to our contention. Coronary artery ligation in dogs caused a 31% decrease in glutamic-oxalacetic transaminase content of the infarcted area of the myocardium and a concomitant 355% increase in serum-activity-transaminase.[29] These investigators also studied glutamic-oxalacetic transaminase and serum-activity-transaminase changes in anoxic rats.[30] Rats were maintained for one hour on 7% oxygen, and then respiratory arrest was induced by further reduction to 3% oxygen. This resulted in a 27% decrease in myocardial glutamic-oxalacetic transaminase, but surprisingly there was no change in serum-activity-transaminase. Since they demonstrated that this was not due to a loss of coenzyme, the authors concluded that a local inactivation of the released glutamic-oxalacetic transaminase must have occurred. No other investigators have repeated this study.

The Degree of Infarction

Other experiments have attempted to relate degree of myocardial infarction to onset, rate of rise and duration of elevation of serum-activity-transaminase. Infarction of the posterior papillary muscle of the left ventricle in dogs caused no change in glutamic-oxalacetic transaminase content of the papillary muscle for the first 40-70 minutes; however the serum-activity-transaminase began to rise approximately 4-6 hours later and reached a maximum of 840 Wroblewski units/ml 18-36 hours post infarction.[31] Some 12-15 hours post infarction the glutamic-oxalacetic transaminase content of the myocardium was decreased to 30-50% of normal. The serum-activity-transaminase usually returns to normal in 4-7 days. It is of interest to note that in myocardial infarction in dogs the type of glutamic-oxalacetic transaminase lost is the soluble fraction.[32] Mitochondrial glutamic-oxalacetic transaminase remains unchanged. Prednisolone administered prior to the infarction will prevent loss of soluble glutamic-oxalacetic transaminase.

Prerequisite of Enzyme Release

These early studies appeared to indicate that necrosis of tissue was a prerequisite to enzyme release, a conclusion reached after rather short-term experiments.[33] The evidence now appears conclusive that cellular permeability changes can occur with a magnitude sufficient to allow glutamic-oxalacetic transaminase to escape into the serum in many conditions. Some investigators have found serum-activity-transaminase levels increased to more than twice the normal levels due to the process of aging.[34] Highman and Altland have shown that exposure to simulated high altitude (32,000 feet) for a short period of time (4 hours) will result in elevated serum-activity-transaminase.[35] This rise has been related to catecholamine release and its effect on cellular permeability rather than to the effects of hypoxia, since epinephrine-in-oil as a pretreatment will exaggerate the response, while Dibenzyline (an adrenergic blocking agent) will diminish the response.

Influence of Exercise

Exercise has also been shown to result in elevated serum-activity-transaminase values. Vacca et al. demonstrated that riding the bicycle ergometer resulted in a rise in serum-activity-transaminase, not due to hemoconcentration caused by sweating.[36] They were of the opinion that cellular permeability was increased by the hypoxic situation existing in the working muscles. The serum-activity-transaminase values continued to rise for at least 2 hours following the exercise but had returned to normal within 24 hours. However, there is other evidence in the literature confirming this view.[37-39] It is of interest to note that physical training (forced walks of 6 hours a day for 17-20 days) enabled rats to walk for 16 hours without any change in serum-activity-transaminase.[39] Untrained animals had large increases in serum-activity-transaminase levels as a result of such exercise. Our laboratory has demonstrated elevated glutamic-oxalacetic transaminase activity in heart, skeletal muscle and liver from exercised rats.[19] The resulting increased gradient of glutamic-oxalacetic transaminase from tissue to serum in these animals would favor increased diffusion of glutamic-oxalacetic transaminase into the serum from the tissues, and perhaps other tissues, and thus might explain, at least in part, the elevated serum-activity-transaminase activity associated with exercise. However, exercise is known to be accompanied by hemoconcentration; thus the elevated serum-activity-transaminase could be merely another reflection of this fact.[40,41]

Extracorporeal Circulation

A final example of a non-necrotic rise in serum-activity-transaminase was found by Walker and Morgan.[42] They observed a rise of up to 100 units/ml after a very short period of extracorporeal circulation. The increase started immediately upon the beginning of cardiopulmonary bypass perfusion and occurred when there was no cardiac or hepatic damage. The authors could offer no explanation.

Clinical Implications

The clinical implications of these observations are clear. There are many conditions in which an elevated serum-activity-transaminase titer does not indicate myocardial damage. A thorough knowledge of the patient's activities of the preceding 24 hours may rule out the possibility of myocardial infarction even though there is an elevated serum-activity-transaminase value. However, the serum-activity-transaminase test has been invaluable as an aid in diagnosis of suspected infarctions. In the most recent studies it was shown that the serum-activity-transaminase level was normal in only one of 379 cases of proven myocardial infarction.[43]

Appearance of Transaminase

The disappearance of glutamic-oxalacetic transaminase from the serum is of considerable clinical importance since "the variability of the serum-activity-transaminase curve in an individual patient parallels the variability of myocardial infarction from patient to patient and underscores the need for serial enzyme determinations obtained as early as possible and at daily intervals thereafter."[43] Also, the rate of disappearance will determine to a large extent the duration of the serum-activity-transaminase elevation.

Dunn et al. in 1958 injected purified glutamic-oxalacetic transaminase intravenously (dogs) and followed its disappearance from the blood.[44] They found ¾ of the injected glutamic-oxalacetic transaminase was gone in 6 hours while the remaining ¼ required up to 72 hours to disappear. Most was lost by diffusion into the interstitial fluid. They found essentially no glutamic-oxalacetic transaminase in the cerebrospinal fluid or urine. A considerable amount of this glutamic-oxalacetic transaminase was excreted via the bile (1,000-2,000 units/24 hours), but it was not correlated with the serum-activity-transaminase levels; thus the investigators tended to disregard this as the physiological route of excretion.

Fleischer and Wakim utilized purified preparations of glutamic-oxalacetic transaminase I (nonmitochondrial) and II (mitochondrial) which they infused intravenously into dogs.[45] They noted that glutamic-oxalacetic transaminase II was cleared from the serum much more rapidly than glutamic-oxalacetic transaminase I.

These investigators reported on this development in much greater detail in 1963.[46] For these experiments they again used glutamic-oxalacetic transaminase I and glutamic-oxalacetic transaminase II. Glutamic-oxalacetic transaminase I, when administered intravenously, moved rapidly into the lymph. It reached maximum activity there in 1-3 hours, and at 30% of the initial serum activity. It required some 4-5 days to be eliminated from the blood to control levels. Urinary excretion was negligible, the total activity appearing in the urine in 48 hours being less than 0.4% of the injected dose. These men demonstrated the decrease in activity in the serum was not due to a loss of coenzyme or to modification (denaturation) of the glutamic-oxalacetic transaminase.

Their studies employing glutamic-oxalacetic transaminase II revealed that it moved into the lymph even more rapidly than glutamic-oxalacetic transaminase I. The maximum activity attained was only 8.6% of the initial serum activity. The urinary excretion in the case of glutamic-oxalacetic transaminase II was also negligible, being less than 0.3% of the administered dose. Only 0.9% of the administered dose of glutamic-oxalacetic transaminase II was present in bile.

Finally, these investigators utilized a substance called "Zymosan." This material causes first an inhibition of, and secondly a proliferation of the reticuloendothelial system. If it is administered 2 hours before the glutamic-oxalacetic transaminase it will delay clearance at first, then later enhance transfer of the enzyme. Their findings are in contrast to those of Henley et al., who reported the enzyme was not sequestered in the reticuloendothelial system.[47]

These are acute experiments, however, and are probably not similar to the conditions existing in myocardial infarction. With infarction there is a gradual progression of dying cells and thus a continued loss of glutamic-oxalacetic transaminase into the serum, which would result in a less rapid clearance of the enzyme from the serum.

Comments

The function of the glutamic-oxalacetic transaminase in myocardial or skeletal muscle remains unknown, but it appears to be closely related to the contractile process.[48] The research carried out in this laboratory indicated that, in general, any condition increasing the work load on a muscular organ results in a elevated glutamic-oxalacetic transaminase content. It is postulated that this may represent an attempt by the organism to convert an increased amount of amino acids to keto acids. The appropriate keto acids could enter the Krebs cycle and result in an elevated production of adenosine triphosphate which would aid the animal in meeting the increased work load. This of course is conjecture and not an established scientific fact.

In summary, it appears that the initial report of LaDue et al.[26] indicating the possible clinical value of the serum-activity-transaminase determination in myocardial infarction has been confirmed and is definitely established as a valuable aid in diagnosis of such cases.

Man

"What a piece of work is a man! How noble in reason! How infinite in faculty! In form and moving how express and admirable! In action how like an angel! In apprehension how like a god! The beauty of the world! The paragon of animals!" "And yet to me what is this quintessence of dust?" — Hamlet-Shakespeare

Nutrition, Cholesterol

CERTAINLY ONE of the most controversial subjects to arise in any discussion of coronary heart disease is the role of diet in the etiology of the disease — particularly the influence of the amount of fat consumed and, more recently, interest in the composition of the fat in the diet.

Physiology of Lipid Digestion, Absorption and Transport[1]

It is estimated that 40% of the ingested triglycerides are completely hydrolyzed to glycerol and fatty acids with the other 60% undergoing only partial hydrolysis to mono- and diglycerides by the lipases in the intestine in the presence of bile acids. These products of triglyceride hydrolysis together with cholesterol, carotenoids and fat-soluble vitamins are absorbed into the intestinal epithelium. Within the epithelial cells resynthesis of triglycerides occurs, and esters of the sterols and vitamins are formed. This mixture of lipids may become associated with small amounts of protein to form chylomicrons which are discharged into the lacteals, then to the thoracic duct and on to the circulating blood. These chylomicrons, then, are the initial vehicles of lipid transport (mostly triglycerides) and are usually visibly present in plasma only when large amounts of absorbed fat must be transported.

β-lipoproteins

Lipoprotein Lipase

The enzyme lipoprotein lipase, which is liberated or activated by heparin, has as its function the "clearing" of the chylomicron triglyceride, effectively hydrolyzing the triglycerides to free fatty acids and glycerol. This "cleared fat" is taken up to a large extent by the liver where the triglyceride is resynthesized, this time as part of the low density β-lipoproteins, and then released into the blood. These β-lipoproteins probably serve as the transport vehicle of the triglycerides to the adipose tissue. It appears that the cholesterol, cholesterol ester and phospholipid constituents of β-lipoproteins are also synthesized and degraded by the liver.

Alpha Lipoproteins

High density α-lipoproteins are also synthesized by the liver, but their role in fat transport is less well understood. There is a suggestion that they may aid in fabrication of the chylomicron by the intestinal epithelial cells through the donation of a peptide. It may also be possible that newly absorbed cholesterol is carried to the liver by the α-lipoproteins, and, if serum albumin is low, α-lipoproteins may carry some nonesterified fatty acids. The α-lipoproteins are also known to serve as carriers of 17-ketosteroids and α-tocopherol.

Fatty Acids

Fatty acids enter adipose tissue as the triglyceride of β-lipoprotein, but they are

and Atherosclerosis*

THOMAS A. ANDERSON, Ph.D.**
Vermillion, South Dakota

mobilized as nonesterified fatty acids. These nonesterified fatty acids are rapidly mobilized by fasting and are also very responsive to the effects of epinephrine.

Susceptibility vs. Lipoprotein Fractions

Attempts have been made to correlate susceptibility to coronary heart disease with elevations in the various lipoprotein fractions. Gofman's Atherogenic Index[2] is an example of a prediction equation designed to measure risk of future clinical coronary disease on the basis of the relative concentration of two serum lipoprotein fractions. Some workers feel that the atherogenic index is no more accurate a predictor than the serum-cholesterol level. There remains little doubt, however, that individuals with a high atherogenic index and/or high serum-cholesterol levels are increased risks for atherosclerotic catastrophes, though not necessarily of the coronary type.[3] It might be noted here that the levels of just about all classes of lipids (phospholipid, triglyceride, cholesterol, lipoproteins) are represented by their champions as the most accurate indicators of risk of coronary heart disease.

The American Medical Association Council on Foods and Nutrition[1] has set a cholesterol level of 280 mg/100 ml. as hypercholesterolemic on the estimate that 95% of the population falls within the range 120-280 mg/100 ml. (average 200 mg/100 ml.). The value for hypertriglyceridemia is given as in excess of 250 mg/100 ml., with 95% of the population falling within the range 30-170 mg/100 ml. (average 100 mg/100 ml.). This is not to say that levels below the limits for hyper-concentration of cholesterol and triglyceride may not be more desirable.

Saturated vs. Unsaturated Fat in the Diet

Regulation of dietary fat intake may have marked effects on serum-cholesterol levels. It was the initial work of Kinsell et al.[4] in 1952 that reported that isocaloric substitution of vegetable oil for animal fat in patients could reduce serum cholesterol and phospholipid concentrations. This fact has been confirmed by a number of other workers.

The choice of animal vs. vegetable or saturated vs. unsaturated to describe the hyper- or hypocholesterolemic effects of a fat is not exactly accurate. For example, butter, which may raise serum cholesterol, contains saturated fatty acids of chain length 6-14 carbon atoms, whereas the saturated fatty acids in lard range from 16-20 carbons and do not appear to be as active in raising serum cholesterol as the shorter-chained fatty acids in butter. Oleic acid, a monounsaturated 18-carbon fatty acid, is not as effective a cholesterol lowering agent as linoleic acid (18:2) or linolenic acid (18:3) or some of the more unsaturated long-chain fatty acids found in fish oil.

Average Diet

The average diet in the United States has a polyunsaturated to saturated fatty acid

(P/S) ratio of about 0.3. In other words, the diet contains approximately three times the amount of saturated fatty acid as unsaturated fatty acids. Wide variations are possible. The polyunsaturated to saturated ratio of safflower oil is nine and for beef tallow the value is approximately 0.04. Diets with polyunsaturated to saturated ratios of one or two are recommended for effective cholesterol lowering.

Mechanism of Reducing Cholesterol

The mechanism by which unsaturated fatty acids reduce serum cholesterol is not completely understood — in fact, opinion on the subject is quite divided.

Influence of Solubility

Wilkens and co-workers[5] theorize that absorption of cholesterol depends upon its solubility in the diet fat. Cholesterol was found to be least soluble in hypocholesterolemic oils and most soluble in those oils affecting the greatest increases in serum cholesterol. The solubility of cholesterol in sunflower seed oil increased with a decrease in the iodine number of the fat, i.e., with hydrogenation or a decrease in amount of unsaturation. This theory may be an oversimplification of a very complex problem, as solubility tests alone are not entirely physiological. However, the findings are of interest and suggest additional study of the phenomenon.

The above theory is contrary to the finding that a polyunsaturated fat, such as trilinolein, compared to tripalmitin, a saturated fat, promotes the absorption of C^{14}-labelled cholesterol and increases its degradation to bile acids.[6] Bile acids represent the major breakdown products of cholesterol. Confirmation of this work by Gordon et al.[7] showed that 0.13 g cholic acid was formed daily by a patient on a butter diet, whereas this figure increased to 0.28 g daily on a corn oil diet.

Still another study by Gerson et al.[7] reported that corn oil lowered the serum cholesterol levels in rats but increased cholesterol biosynthesis and also the tissue content of cholesterol in the heart, aorta, liver, gut and muscle. No change was noted in body cholesterol as a whole, but the increased sterol excretion indicated greater biosynthesis and greater excretion.

Species Difference

There may be a species difference here, since a recent report by Taylor et al.[8] indicated that cholesterol biosynthesis in man may be constant and does not vary with the amount taken in the diet. Theoretically, then, any dietary constituent which would accelerate cholesterol degradation would be of value in lowering serum cholesterol.

The literature is replete with studies of the dietary habits of coconut-eating Polynesians, Eskimos and monks, each study attempting to correlate serum-cholesterol levels with the incidence of cardiovascular problems. Take, for example, the study of Trappist and Benedictine monks.[9] Trappists exist on a frugal vegetarian diet (26% fat), don't heat the rooms in the monastery, don't talk much, and were found to have serum-cholesterol levels lower than those found in Benedictines who were comparatively more affluent, consuming a mixed diet (43% fat). However, no difference in electrocardiographic indication of cardiovascular disease between the two groups was found. This would appear to deter those who equate an increase in blood cholesterol with increased susceptibility to coronary attacks. But no! Keys[10] reexamined the data and concluded that there was sufficient evidence to suggest that Trappists are less prone to coronary heart disease than Benedictines — so the controversy continues.

The Framingham Study[11] has shown that the incidence of coronary heart disease increases with a high serum-cholesterol level; but this same study concluded that there was no significant correlation between the various dietary components and the serum-cholesterol level. These workers suggest the possibility that the diet may have passed some threshold level of cholesterol, fat or some other constituent, beyond which further increment is not associated with an increase in serum cholesterol.

George Mann[12] pretty well sums up the problem in his statement that:

> "The evidence will not support the hypothesis that diet causes coronary heart disease, but the evidence does indicate that a reasonable diet will affect a lowering of levels of total cholesterol in many people and there is reason to suppose that this will reduce the risk of coronary heart disease, even though we cannot prove that supposition."

Mann further suggests that certain patients use the dietary regimens outlined by the American Heart Association[13] and the American Medical Association.[1] He feels that this course of action would be especially appropriate for persons with the high-risk attributes of hypercholesterolemia, hypertension and familial coronary heart disease.

One final note on the relationship of hypercholesterolemia and hypertension and risk of coronary heart disease. Cornfield[14] has presented a very sophisticated, yet convincing, statistical model which indicates a 5-fold difference in risk of coronary heart disease between the upper 5% and lower 5% of the population with respect to serum cholesterol or systolic blood pressure alone, but a 25-fold difference between those who are in the upper 5% of the population with regard to both variables (blood pressure and cholesterol) and those in the lower 5% with respect to both variables.

Effect of Pattern of Food Intake on Lipid Metabolism

The work of Cohn[15] has shown that rats force-fed twice daily the same amount of food they would normally consume in 20-30 small snacks throughout the day evidenced the following: increased body fat, altered thyroid activity, increased urinary nitrogen excretion (decreased utilization of protein) and higher cholesterol levels. He found similar responses in chickens, producing hypercholesterolemia and atherosclerosis by limiting the time of exposure to feed.[16] Since the major calorie load must be metabolized after the evening meal in urban populations, Cohn feels that there might be an advantage in re-education with respect to eating habits. He also suggests that livestock producers should mechanize their feeding practices to produce a leaner product with less animal fat in one of our most important protein sources. It would appear that nutritional surveys should consider how the food is consumed as well as what is eaten.

Smoking and Blood Lipids

There seems to be a pretty definite correlation between smoking and risk of coronary heart disease. The action of nicotine on the cardiovascular system is still the subject of much dispute, particularly as to its effects on the coronary circulation. In a study by Kershbaum and Bellet,[17] cigarette smoking has been shown to cause a rise of 25% in free fatty-acid levels of normal individuals; but in patients with myocardial infarction the elevation was as high as 65%. The rise in free fatty-acid was paralleled by a concomitant increase in urinary catechol amines.

This study also suggested that some impairment of fat tolerance appeared to be caused by cigarette smoking, since post-alimentary lipemia was noted in some patients.

Experiments in dogs showed a hypercholesterolemic response to intravenous nicotine administration, but the extrapolation of this finding to man is questionable.

These effects are apparently the result of epinephrine release which is presumably stimulated by nicotine. Sympathetic ganglionic blockade or adrenalectomy inhibits the effect of smoking on plasma-free fatty-acid levels. So, in addition to the effects of smoking and presumably nicotine on blood pressure and peripheral resistance, we have marked alterations in lipid metabolism.

The above-mentioned study utilized filter cigarettes. It may be that the ultimate test of a good filter would be one that could effectively inhibit the rise in plasma-free fatty-acid levels. You are all familiar, I'm sure, with the slogan LSMFT. I can just visualize, as cigarette advertising becomes scientific, a cigarette company coming out with a slogan which would read LRPNEFAL* — meaning, less rise plasma nonesterified fatty acid levels.

Exercise and Blood-Lipid Levels

Probably the most dramatic reports of the influence of exercise on blood-lipid levels concern the various groups of lumberjacks studied[18] who may consume anywhere from 5000-8000 calories daily with from 200-400 g. of animal fat, yet still maintain serum-cholesterol levels in the normal range.

---

*See Test Your Word Score Page 1333.

Gsell and Mayer[19] compared the serum-cholesterol level of the population of a Swiss Alpine village to that of a working class group of similar ethnic origin in the city of Basel. These authors conclude that such dietary factors as the fat content and proportion of saturated and unsaturated fats are probably important in determining the serum-cholesterol level, but "they are less important than the activity factor or they manifest their importance only in physically inactive populations."

Exercise causes a decrease in turbidity of postprandial plasma and an increase in fat utilization, apparently affected by an increase in lipoprotein lipase activity. Another important advantage of adequate exercise is the utilization of a portion of the caloric intake, which is commonly in excess of need. Of course, the advantages of regular exercise extend beyond the effects noted on lipid metabolism; developing a pattern of living which includes some daily physical exertion (in moderation) will help to maintain muscle and vascular tone through the years and also serve as a form of relaxation.

Summary and Conclusions

When one adds the effect of dietary lipids on blood-clotting time and fibrinolysis, as well as the contribution of stress and hypertension, to the risk of coronary heart disease, the list of predisposing factors becomes quite formidable.

What approach to take in the management of the disease? It certainly can't be accomplished through the consideration of diet alone or the management of blood pressure alone. It must rather be a combined approach, just as coronary heart disease itself is influenced by a complex combination of metabolic, mechanical and hormonal factors.

A concerted educational program will be needed to publicize some of the danger signals of approaching coronary heart disease. A highly competitive, middle-aged, slightly obese individual who is a sedentary, heavy smoker with an elevated blood pressure and serum-cholesterol level should have been alerted many years previous to his present condition that he will be a good bet to suffer some sort of cardiovascular accident if he doesn't change his living habits. The American Cancer Society has publicized the seven danger signals of cancer; possibly those with an interest in cardiovascular disease could come up with a similar program establishing danger signals for coronary heart disease.

Preventive medicine seems to be the obvious answer. Counselling on weight control, diet, daily exercise, and certainly on the development of some suitable philosophy of life to enable one to compete adequately without undue stress — all this to be achieved before the first signs of trouble.

I am not suggesting that one set formula can be developed to fit each individual situation: surely the accountant commuting into Los Angeles competing with his fellow commuter for the Sepulveda Boulevard turnoff will react differently to a given amount of fat in the diet than, possibly, a Trappist monk or a South Dakota farmer. However, I, for one, would like to see a more forceful program of education undertaken by those interested in cardiovascular disease to alert people to the possible dangers of improper diet, hypertension, smoking, etc.

Cardiovascular disease is a disease of the affluent society. The objective, as I see it, lies in making suitable adjustments to this environment which we have created for ourselves.

LOMOTIL—*Pharmacologic Activity.*

The significant pharmacologic actions of Lomotil are summarized as follows:

Evidence indicates that Lomotil acts directly by inhibiting excess peristalsis.

Lomotil is not known to inhibit nonpropulsive intestinal movements.

Roentgenograms demonstrate that this activity occurs within two hours after oral administration and persists for at least six hours.

Studies in the rat show Lomotil to be more effective in inhibiting fecal excretion than either codeine or morphine.

Analgesic, anticholinergic, mydriatic and gastric secretory effects have not been significant.

Reduction of propulsive motility with Lomotil relieves spasm and cramping, allows physiologic absorption of fluid and reduces frequency of evacuations to provide prompt, symptomatic control of virtually all diarrheas.

LOMOTIL® tablets liquid

Each tablet and each 5 cc. of liquid contains:
diphenoxylate hydrochloride ....2.5 mg.
(Warning: May be habit forming)
atropine sulfate ....0.025 mg.

slows propulsion · relieves distress · stops diarrhea

Precautions: Lomotil is an exempt narcotic preparation of very low addictive potential: more than three million prescriptions have now been written for Lomotil. Recommended dosages should not be exceeded. Lomotil should be used with caution in patients with impaired liver function and in patients taking addicting drugs or barbiturates.

Side Effects: Side effects are relatively uncommon but among those reported are gastrointestinal irritation, sedation, dizziness, cutaneous manifestations, restlessness and insomnia.

Dosage: For full therapeutic effect – Rx full therapeutic dosage. The recommended initial daily dosages, *given in divided doses,* until diarrhea is controlled, are:

Children:
3 to 6 months–3 mg. (½ tsp.* t.i.d.)
6 to 12 months–4 mg. (½ tsp. q.i.d.)
1 to 2 years–5 mg. (½ tsp. 5 times daily)
2 to 5 years–6 mg. (1 tsp. t.i.d.)
5 to 8 years–8 mg. (1 tsp. q.i.d.)
8 to 12 years–10 mg. (1 tsp. 5 times daily)

Adults: 20 mg. (2 tsp. 5 times daily or 2 tablets 4 times daily) **Based on 4 cc. per teaspoonful.*

Maintenance dosage may be as low as one fourth the therapeutic dose.

Lomotil is a brand of diphenoxylate hydrochloride with atropine sulfate; the subtherapeutic amount of atropine is added to discourage deliberate overdosage.

SEARLE *Research in the Service of Medicine*

Butazolidin®
brand of
phenylbutazone

in painful shoulder

Geigy

Therapeutic Effects

The acute phase of subdeltoid bursitis, tendinitis and associated periarticular inflammation usually responds promptly and dramatically to Butazolidin, brand of phenylbutazone. Pain and tenderness may be relieved within 24-48 hours and mobility of the affected arm quickly restored. Full recovery is frequently achieved within 7-10 days so that therapy is generally of short duration. Calcific deposits are not specifically affected by treatment, but their presence does not appear to retard symptomatic improvement.

Phenylbutazone has not replaced physiotherapy, x-ray treatment, or local injections of hydrocortisone in the more chronic conditions, but it may advantageously be combined with these measures.

Contraindications

Edema, danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. Because of the increased possibility of toxic reactions, the drug should not be given when the patient is senile, or when other potent chemotherapeutic agents are given concurrently. Large doses of Butazolidin alka are contraindicated in patients with glaucoma.

Precautions

Before prescribing, the physician should obtain a detailed history and perform a complete physical and laboratory examination, including a blood count. The patient should be kept under close supervision and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools. Regular blood counts should be made. The drug should be used with greater care in the elderly.

Warning

If coumarin-type anticoagulants are given simultaneously, the physician should watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea and sulfonamide-type agents and insulin. Patients receiving such concomitant therapy should be carefully observed for this effect.

Adverse Reactions

The most common adverse reactions are nausea, edema and drug rash. The drug may reactivate a latent peptic ulcer. Infrequently, agranulocytosis, generalized allergic reaction, stomatitis, salivary gland enlargement, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia are also possible side effects. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently.

Average Dosage

Initially, give 400 mg. daily (one tablet or capsule q.i.d.), reducing this, if possible, when a favorable therapeutic effect has been obtained. If after one week there has been no response, discontinue the drug. To minimize gastric distress, Butazolidin alka capsules may be the preferred form.

Note: The physician should be fully aware of dosage, precautions, adverse reactions, and contraindications as contained in the complete prescribing information.

Butazolidin alka

Each capsule contains:	
Butazolidin, brand of phenylbutazone	100 mg.
dried aluminum hydroxide gel	100 mg.
magnesium trisilicate	150 mg.
homatropine methylbromide	1.25 mg.

Butazolidin
brand of phenylbutazone
Tablets of 100 mg.

The Place of the Basic Sciences in Postgraduate Medical Education

It is generally accepted in undergraduate medical education that a student must be firmly grounded in the basic sciences of anatomy, biochemistry, microbiology and pathology before he can understand the clinical subject matter presented to him later in medical school. After he graduates, he becomes eligible for postgraduate education, which is concerned mainly with new clinical knowledge and techniques of value in everyday practice. In some respects, postgraduate teaching is an extension and amplification of the clinical years of medical school. It assumes that the physician has an adequate command of the prerequisite basic science information necessary for understanding the advanced clinical instruction.

Now it is possible that the organizers of many of the postgraduate programs being offered today overestimate the average physicians' current understanding of the basic sciences. Many doctors readily admit that their knowledge of these subjects has faded and express a need to review them as well as to learn about newer developments in these fundamental fields. Thus, there definitely is a need for basic science education for the practising physician.

However, when it comes to planning or attending medical programs, doctors tend to select those that deal with highly practical clinical topics. This preference is evident in most of the programs of scientific meetings sponsored by medical schools, hospitals and medical societies. Also, a strong clinical orientation is seen in the majority of the more formally organized courses of which the American Medical Association has compiled a list of 1,569 for 1964-1965. For example, less than 40 of these courses can be identified from the titles as being primarily of basic science nature and designed for the general practitioner.

We believe that if a physician has a better understanding of the fundamentals upon which modern diagnosis and therapy are based he will be able to practice a better brand of medicine. This conviction motivated us in the development of the program, "Basic Mechanisms of Heart Disease," portions of which are published in this symposium. The course was designed to provide the practising physician increased knowledge of the fundamental aspects of medical science which apply to the cause, prevention, diagnosis and treatment of heart disease. It was presented

**Happily,
not all your patients
are overweight**

**but
for those who are...**

Bamadex®
d-amphetamine sulfate (15 mg.) and meprobamate (300 mg.)
Sequels®
Sustained Release Capsules

Most overweight patients could benefit from the appetite control provided by the prolonged anorexigenic-tranquilizing action of BAMADEX SEQUELS: anorexigenic action through the central stimulant effect of the amphetamine; tranquilizing action with only mild sedation through meprobamate; prolonged action through sustained release of active ingredients.
Contraindications: Hyperexcitable and prepsychotic states; patients hypersensitive to meprobamate.
Side Effects: Occasional allergic skin reactions may occur with meprobamate, accompanied by fever, nonthrombocytopenic purpura, angioneurotic edema, hypotension, or bronchial spasm. Drowsiness with or without ataxia and/or alteration in visual accommodation may occur. Effects of alcoholic beverages may be increased by meprobamate. Use with caution in patients with coronary or cardiovascular disease or severe hypertension. Prolonged use may result in dependence. Reactions can occur if drug is not withdrawn gradually.

LEDERLE LABORATORIES • A Division of AMERICAN CYANAMID COMPANY, Pearl River, N.Y. Lederle

mainly by the basic science faculty of the University of South Dakota School of Medicine. Subjects included the anatomy and the ultrastructure of the heart, ventricular arrhythmias, the origin and fate of serum transaminases, nutritional factors in the genesis of heart disease, the coronary blood flow, chemistry of heart failure and electrolyte alterations in cardiac disturbances, the response of the myocardium to drugs, the action of normal and abnormal heart valves, and the fundamental nature of heart sounds. In the pathology laboratory the physician was able to personally examine a large number of gross heart specimens and microscopic sections representative of various diseases. The attempt was made throughout the course to provide clinical correlation where possible.

Basic science education is an integral part of continuing education for the practising physician, and it deserves more emphasis in the future. If the physician has a good understanding of the basic biological mechanisms which underlie clinical problems, he will be better able to manage these problems. He will also be in a better position to profit from the many programs of advanced clinical instruction. All of this will give greater assurance that postgraduate education will eventually be translated into improved care for the patient.

Value of the Two-Year Medical School

BEING AN alumnus of the University of South Dakota and having studied medicine for two years at the same university before transferring to Washington University School of Medicine, where I received my degree of Doctor of Medicine, I have watched with interest the gradual decrease in the number of two-year medical schools in the United States. Ten years ago there were 74 four-year medical schools and six two-year medical schools in this country. In the six two-year medical schools (the University of Mississippi School of Medicine, University of Missouri School of Medicine, Dartmouth Medical School, University of North Dakota School of Medicine, State University of South Dakota School of Medicine, and West Virginia University School of Medicine) 438 students were enrolled. In the 74 four-year schools, 14,079 students were enrolled in the first two years. Thus, approximately 3 per cent of all the students in the first two years of medical school were in the two-year schools. In 1964 the number of two-year medical schools had decreased to three, just half the number that existed ten years ago. The three remaining two-year schools are Dartmouth Medical School, University of North Dakota School of Medicine, and University of South Dakota School of Medicine with a combined enrollment of 271 students. The number of four-year schools in 1964 was 84 with a combined enrollment of 16,948 students in the first two years. Thus, about 1.5 per cent of all medical students were in the two-year medical schools.

The three two-year schools have been in existence longer than fifty years. The two state schools in North Dakota and South Dakota were established in 1905 and 1907, respectively. Dartmouth, however, was established in 1797 and is the third oldest medical school in America, being antedated only by Columbia University College of Physicians & Surgeons in 1769 and by Harvard Medical School in 1783.

Medical education is the most expensive of all types of education, and because the two clinical years are proportionately more expensive than the basic or preclinical years,

On Stelazine® brand of trifluoperazine
she's calm and alert

When a tranquilizer is needed, 'Stelazine' can regulate the level of anxiety so that the patient is unlikely to overreact to stress but is not tranquilized into psychic inertia. Patients on 'Stelazine' often experience a sense of mental alertness and, because they feel so much better, are more interested in their normal activities.

Contraindicated in comatose or greatly depressed states due to CNS depressants and in cases of existing blood dyscrasias, bone marrow depression and pre-existing liver damage. *Principal side effects,* usually dose-related, may include mild skin reaction, dry mouth, insomnia, fatigue, drowsiness, dizziness and neuromuscular (extrapyramidal) reactions. Muscular weakness, anorexia, rash, lactation and blurred vision may also be observed. Blood dyscrasias and jaundice have been extremely rare. Use with caution in patients with impaired cardiovascular systems.

Before prescribing, see SK&F product Prescribing Information.

the cost of operation of a four-year medical school is proportionately greater than that of the two-year medical school. It is impractical for some states whose populations are small to attempt to maintain a four-year medical school, not only because of the added expense but also because of the lack of clinical material, which is necessary for the two clinical years.

Whereas it may be theoretically desirable for a student to obtain his entire medical education at the same school, such is not necessarily the case. In fact, there are certain advantages associated with transfer from one institution to another, such as is practiced in European universities. It is possible for the European student to transfer from one institution to another for varying periods of time and to return to the parent institution if he wishes. This permits greater flexibility and presumably provides more mature and broader training.

In addition to the impracticality of maintaining four-year medical schools by certain institutions, such as those in New Hampshire and in North and South Dakota, are such schools undesirable from the standpoint of training a medical student? From personal experience, I am convinced that not only is there no disadvantage but probably a real advantage in attending such a school, because the emphasis is placed exclusively on preclinical teaching; also because of the smallness of the institution, students are more likely to apply themselves intensively and to have closer contact with the faculty.

Unfortunately, the attrition in the first two years of medical school is relatively high. Whether this represents poor selection of candidates for admission to the Freshman class or is due to other reasons, it is difficult to say.[1] The attrition in the first year classes of all medical schools for 1963-1964 was 7.5 per cent; in the second year classes, 3.3 per cent; in the third year classes, 1.2 per cent; and in the fourth year classes, 0.7 per cent. Because of the relatively high attrition at the end of the first two years, the four-year schools usually have vacancies which can be filled by transfers from the two-year schools. Administrators of four-year schools have learned that transfers from schools with which they have had experience have proved satisfactory. Most transfers from two-year medical schools have been to Harvard Medical School. In 1963-1964 "The total number of 26 students transferring from two-year schools to Harvard was more than twice as many as to any other school. Seven schools (Harvard 26, Minnesota 11, Northwestern 9, Marquette 6, Iowa 5, Temple 5, and Wisconsin 5) accounted for about 70 per cent of the students transferring from two-year schools."[1] It is considered difficult to gain admission to Harvard Medical School, and the fact that the largest number of transfers were to this school indicates that students completing two years at the two-year school are well trained and able to maintain their standing with those who have had their first two years at Harvard Medical School. For many years Tulane University School of Medicine accepted transfers from the then existing two-year schools in the South — Mississippi, Alabama, and Florida — and with few exceptions, these transfers did as well as the students who received their first two years of training at Tulane.

Dr. Walter L. Hard,[2] Dean of the School of Medicine at the University of South Dakota, stated that failure of students receiving their first two years of medicine at his school to graduate after transfer to a four-year school is practically nil. "Indeed, in my nineteen years at this school, I know of only two students who failed to complete medical school, and both of these were for psychiatric reasons. Furthermore, I know of only two students who found it necessary to repeat a year, either junior or senior." Of the 650 medical students during Dean Hard's tenure, 75% have graduated in the upper half of their classes. When one compares this record with the experience with the four-year medical schools in which the attrition in the junior and senior years is 1.2% and 0.7% respectively, the two-year schools (at least the State University of South Dakota and presumably the others as well) are doing an excellent job.

There is unquestionably a need for an in-

crease in the number of medical schools to train enough physicians to take care of our rapidly increasing population. Because of state pride the individual states want to have four-year medical schools. This is understandable; but, before embarking on a four-year medical school program, the state should determine whether it is financially able to maintain the expensive third and fourth years, and also whether it is large enough to furnish sufficient clinical material for teaching purposes. The legislatures must be informed of the tremendously increased cost of the four-year school so that if the state is financially able to support it, the legislature will provide the necessary funds to operate the school. Too frequently the costs of a four-year medical school are compared with those of a liberal arts school, and, of course, such a comparison is ridiculous.

An additional advantage of attending a two-year medical school is that generally the cost is much less than it is at a four-year medical school. Obviously, state supported schools have lower tuition than private schools, because they are tax supported. Of the 84 four-year medical schools today, only four have tuition as low as the two state two-year schools. All four are also state schools. In 34 state schools the tuition is higher than in the two two-year state schools. Living expenses are generally less at two-year schools because these schools are in small communities where the medical student can live on a lower budget than if he were attending some of the larger institutions.

A theoretic disadvantage of attending a two-year medical school is that its program might not be correlated with the third and fourth years of the four-year schools. Because, however, most students who have completed the first two years in a two-year school are accepted by a four-year school which has accepted many transfers from that school for many years, more often than not the courses in the two-year school have been planned so that they correlate with those of the four-year school. Therefore, this is not a valid disadvantage. Even if it were, it would be far offset by the advantages of transferring to another institution, a practice greatly encouraged in European universities. At present even among the four-year schools there is an increasing tendency to permit transfer to another institution for one semester on an elective basis. This is highly desirable because it permits the student to obtain a particular phase of training in a branch of medicine in which he is especially interested. In fact, in 1964, 105 students transferred from 50 four-year schools and 47 from other schools, 58 in the third year, and 47 in the second year.

Probably for some time two-year medical schools will continue to exist. Although many medical educators hope that the two-year medical schools can be eliminated, it is my firm conviction that they occupy a real place in modern medical education and that they are serving a distinct purpose. It is far better for sparsely populated states, such as South Dakota and North Dakota, to maintain an efficient two-year medical school than to overextend themselves financially and maintain a second-rate four-year medical school.

to help relieve pain in common anorectal disorders

"non-caine" Diothane®

Diothane—with its chemically distinct "non-caine" anesthetic agent diperodon—provides effective temporary topical anesthetic and emollient actions for soothing relief of anorectal pain. Anesthetic activity is effective and relatively prolonged; sensitization is infrequent. Reports to Merrell on 1,500 patients treated pre- and postoperatively with Diothane Ointment, indicate only 22 developed local skin reactions. Reactions to Diothane have been burning or stinging sensations and a few cases of allergic manifestations. An additional advantage: Diothane Ointment and Suppositories are mildly antiseptic. Prescribe or recommend either form...both are now available.

DIOTHANE OINTMENT

COMPOSITION:
diperodon 1.0%; oxyquinoline benzoate 0.1% in a special ointment base.

INDICATIONS:
Provides temporary palliation of pain that may result from hemorrhoidectomy and from common anorectal disorders such as hemorrhoids, anal fissures, pruritus ani.

DIOTHANE®
OINTMENT

CHILL
↑PULL APART↑

DIOTHANE SUPPOSITORIES

COMPOSITION:
Each suppository, weighing approximately 2.6 Gm., contains diperodon 1.0%; urea 10.0%; oxyquinoline benzoate 0.1% in a special hydrophilic suppository base. A unique shape keeps the suppository in intimate contact with mucous membranes.

INDICATIONS:
Provide for temporary palliation of pain caused by hemorrhoids and pruritus ani.

The Management of Obesity

NATIONWIDE, MILLIONS of Americans today desperately wish to lose weight. They count calories, go on weird diets, try drugs, join reducing clubs, get advice from radio, TV, and printed articles; many consult their physicians. The results are sometimes spectacular, as witness the announcements by TOPS ("Take Off Pounds Sensibly") of the statistics of their award winners; a loss of "only" one hundred pounds in a year by a woman doesn't come near qualifying for "Queen of Minnesota Tops." (A mere 38-pound loss may be enough for the "King"). But in too many cases the end results are vastly disappointing; either the weight loss is trivial or it is only temporary.

The management of obesity is notoriously a frustrating business; the family physician spends endless time to little avail and concludes that most would-be reducers are inveterate liars; the bathroom scale threatens doctor as well as patient with neurosis. Most obesity clinics and special reducing centers consider their performance above par if in 20 per cent of their patients they obtain a sizeable reduction that is maintained as long as a year.

The worst of it is that it all should be so simple: merely a matter of caloric balance; and tables of calorie values of foods, as well as "foods" with little or no calorie value, are available everywhere. But it is not all that simple. In the first place, it is increasingly apparent that in many cases of obesity, and in the majority of obese children, the abnormality is more on the side of energy expenditure than in the direction of an unusually large food intake. These people exercise too little, they reduce physical activity to a minimum, and when they reluctantly abandon the sedentary posture they move with deliberation; in short, the obese person is apt to be uncommonly successful in energy economy.

It is helpful to realize this fact, but this in itself is no guarantee of success. Getting fat persons to exercise is seldom much easier than to persuade them to stop eating. Besides, it takes more than a few minutes of calisthenics to add up to an appreciable amount of calories.

Ideally, more exercise and less food is the answer; the real target should be to shed fat and to exchange some of the lost fat for more muscle. A pound of weight loss is, on the average, the equivalent of about 3,000 calories of negative balance; a pound of muscle gained corresponds to less than 500 calories of positive balance.

We have discussed these questions in enough detail for patients and most physicians in "Eat Well and Stay Well" (revised edition, Doubleday, pp. 65-99). The needed calorie data on foods are in a table available from "Consultant."*

The purely technical questions are easy; the psychological aspects are much more complicated and their exploration in depth with the individual patient eventually could lead to the psychiatrist's couch. This is not to imply that obese patients are generally neurotic or should be referred to a psychiatrist. In the absence of indications for neurosis other than simply the fact of obesity, we would caution against over-emphasis on this approach.

But, however we rate the emotional factor in the scale of causes of obesity, it is clear that the successful management of obesity demands awareness of the psychological situation. Plenty of patients insist they want to reduce, know that calorie imbalance is the problem, understand the rudiments of calorie values, of food and exercise and still cannot, or at least do not, reduce. Obviously, psychological as well as dietetic problems must be solved.

Fantastic reducing diets, featuring bizarre combinations of food, are periodically promoted and, to the annoyance of serious students of metabolism, they are often at least temporarily successful with some people. In part the explanation is that the re-

You've Made Us Change

APACHE MEDICAL COMPLEX

We started with plans for the most modern, most efficient, most tenant-oriented *medium-sized* medical complex in Minnesota. Your response forced us to change our plans. Now we're going to construct the most modern, most efficient, most tenant-oriented *large-sized* medical complex in Minnesota, to be built at Apache Plaza in two medium-sized stages. Stage 1, pictured above, will be ready for you in **Fall, 1966.**

Here are some of the reasons why Apache Medical Complex will be the ideal location for your new office:

- Ample free parking for everyone, reserved parking for doctors.
- Convenient for patients and staff, part of a 60-store shopping complex.
- Handy to Twin Cities hospitals.
- Attractive, dignified building, giving you the best professional address north of either loop.
- Complete facilities, including pathology and radiology laboratories.
- Essential ancillary services and shops.
- Restaurant facilities conveniently located for doctors, patients and staff.
- Modern building techniques will give total flexibility to your office space-planning.

APACHE MEDICAL COMPLEX

ducer, caught up in the enthusiasm about a "wonderful new discovery," has new hope, and therefore more will, for real reduction. Perhaps more important is the ego-satisfaction of doing something new, in the latest style, so to speak, and of attracting commiseration for eating such an awful mess. Here is a conversation piece, an attention catcher, that is far more interesting than simply eating less of an ordinary diet. If one must be constantly hungry, some recompense of awe or special sympathy is a great help.

Recently, periods of total starvation have been advocated as an approach to the "hard" cases of extreme obesity.* In the April issue of this journal, Schultz, Werner and Kerlow report on their satisfaction with this method from the experience with 12 patients whose body weights averaged 186 per cent of the so-called "ideal" weight. They ate no food at all for 13 days, lost an average of 23 pounds, reported decreased appetite, and "no serious clinical side effects were observed."

Long ago we observed that total abstinence from food quickly results in loss of appetite; indeed a sense of incipient nausea may develop in a few days, especially if the person engages in physical activity. And the fatter the patients, the better they tolerate such starvation. But even nonobese people get along remarkably well for several weeks with no food if they are sedentary. The professional fasters who attracted attention at the turn of the century often insisted on an unusual sense of well being, even at the end of three or more weeks of fasting; Succi, who was not fat to begin with, had no ill effects from forty days without food.

The professional fasters, besides monetary reward, had much satisfaction from the great attention they received. The obese persons who are given no food at all for a couple of weeks, also enjoy this reward of attention, especially if their heroic feat is undertaken in full view of the hospital staff. And they find they certainly can lose weight.

It is questionable how well the starvation approach will work for the nonhospitalized patients. The constant medical attention is probably unnecessary for their safety but it may be essential for its psychological effect.

Perhaps we should mention drugs that depress the appetite. In selected cases these may be helpful and even advisable for brief periods of time. But they have undesirable and possibly dangerous side-effects and we cannot encourage their general use.

The obesity problem will be with us for a long time to come. It is promoted by an over-abundance of food of high caloric density which we are persuaded to over-eat by all the skills of constant advertising. Often, too, our appetites are increased and our judgments dulled by too much alcohol which by itself adds many calories. And while our calorie intake goes up our output goes down. The wonderful advances of technology not merely free us from back-breaking toil; they make it almost impossible to get a decent amount of calorie-using exercise.

But we trust that we shall not simply give in and accept gluttony and physical indolence as necessary accompaniments to our modern way of life, essential for the food and automobile industries so central in our national economy. We can start with the young and stop the pernicious custom of praising "fine, fat" babies. In the school years we should take a hard look at the high calorie density menus thrust at the youngsters whose only exercise turns out to be some three hours a week in "phy. ed." As civilized adults we can insist that good foods should not be defined as the "richest" and that good cookery does not necessarily mean thick gravies, butter or margarine on everything and dessert "a la mode." We can cultivate contempt for the effort to avoid physical activity. And we can emphasize the fact that in both sexes and at all ages obesity is disgusting as well as a hazard to health.

Cancer of the Stomach

THROUGHOUT THE years the techniques of surgery, anesthesia, and preoperative and postoperative care have been greatly improved. The result has been an encouraging improvement in curability and a decline in operative mortality and morbidity. The results of surgical treatment of carcinoma of the stomach at the Mayo Clinic have been analyzed recently; this study involved 11,817 cases.

At present in our institution, subtotal radical gastrectomy for curative purposes is associated with a mortality of less than 5%; the five-year survival rate obtained with this operation is 50% when the lymph nodes are not involved and 20% when the lymph nodes are involved. The over-all five-year survival rate is about 34%, and we have observed, in the more recent review of our cases, that there is a trend for this rate to improve even more.

In our experience with radical total gastrectomy, the operative mortality has been 14% and the five-year survival rate, about 10%. It should be mentioned that these data apply to adenocarcinomas of the stomach. When the tumors are of the sarcoma type, the mortality with these operations is the same, but the five-year survival rate is considerably higher (about 44%).

At present, of the total number of patients in whom carcinoma of the stomach is diagnosed at the Mayo Clinic, 90% are subjected to laparotomy; the remaining 10% are found to have evidence of widespread metastasis, and surgical exploration is therefore not indicated. Fifty-five per cent are treated by resection; 3 to 4% die at the time of or immediately after operation. Of those who survive the resection, 19% live more than three years after the operation and 15% live more than five years.

The physician should always be alert to detect malignant tumors of the stomach at an early stage. In the treatment of this disease, the histologic classification of the lesion, the mode of spread, and the surgical indications should be borne in mind. Adequate surgical treatment of these tumors offers reasonably satisfactory results with an acceptable operative mortality.

Should it make any difference to her that the "500 Viso" won every major design award this last year?

Two-dozen judges think so...

What these professional designers and engineers saw in the "500 Viso" is what anyone taking a cardiogram is looking for: quick and simple patient connection . . . easy-to-find-and-use instrument controls . . . clear, accurate recordings free from common artifacts and "AC" . . . rugged construction to withstand the inevitable jolts of day-to-day usage . . . and real portability proven by light weight and a slim, compact size.

From Industrial Research, the 1964 Western Electronics Conference, Product Engineering, Industrial Design, and the Aluminum Company of America, many distinguished panels of judges cited the "500 Viso" for its outstanding achievement of the objectives of superior ECG design.

And during the past year, these same merits of the "500 Viso" have also been recognized by several thousand other "judges" — your colleagues in the medical profession who now own a "500". To them the convenience, performance and attractiveness of this modern ECG represents excellent value at $695 delivered, continental U.S.

Letter to the Editor:

I am sure that all physicians in this state, including the pathologists, have read with interest Dr. S. A. Smith's special article concerning cervical cytology in the February, 1965 issue.

According to this article, 27.4 per cent of Minnesota physicians stated that they did not take routine pap smears. Cost was one of the factors and "the suggestion was often made that the state establish a laboratory to process smears free or at cost." (I question the use of the work "free," unless there are physicians in the state of Minnesota who do not pay any taxes).

If the state were to operate a laboratory, its overhead would probably be no less than the overhead of the pathologists who presently examine the cytology smears in this state. An effective cytology screening program must be closely supervised and controlled by M.D.s specially qualified in cytology.

Doctor Smith's article points out that the great majority of eligible females in the state of Minnesota are being surveyed on a routine basis, with the smears being sent by the local physicians to qualified pathologists. This certainly precludes the need for a state-operated diagnostic cytology laboratory.

The Editor's Soliloquy

A Thousand Torches from One Small Flame

The measure and quality of success may require their own definitions for adequate evaluation. That success which is self-directed for personal glory alone is neither permanent nor admirable, as it makes fools falsely esteemed, secretly envied, and servilely flattered by those obsequious ones who love to sit in the shadow of idols. Genuine success is self-effacing. Its vision encompasses all mankind.

In reviewing graduates from the University of South Dakota the roster includes some internationally recognized men: Alton Ochsner (surgeon), Roger D. Reed (penicillin), Harold F. Schuknecht (operation to relieve deafness), Ernest Lawrence (cyclotron designer — instrument to split the atom); the list is too long to be catalogued here; but these few notable figures who have had world-wide impact in the field of medicine amply support the thesis that eminence can emerge from the most humble origins as well as from established-name institutions, and that true success is altruistically, not selfishly motivated and achieved.

To the University of South Dakota, then, may be traced some of the beginnings of a new era — the most super civilization of all time — the age of intellectual pragmatism,* the revolutionary benefits of which, if not foolishly dissipated or misdirected by the politically ambitious, can usher in a neo-millenium.

Carl O. Rice, M.D. U.S.D.'23

Stress formula vitamins are an important supportive measure in maintaining the nutritional status of the emotionally disturbed patient. With STRESSCAPS, B and C vitamins are present in therapeutic amounts to meet increased metabolic demands. Patients with anxiety, and many others undergoing physiologic stress, may benefit from vitamin therapy with STRESSCAPS.

STRESSCAPS®

FOR PROFESSIONAL RECOMMENDATION ONLY

Stress Formula Vitamins Lederle

Each capsule contains:

Vitamin B_1 (as Thiamine Mononitrate)	10 mg.
Vitamin B_2 (Riboflavin)	10 mg.
Niacinamide	100 mg.
Vitamin C (Ascorbic Acid)	300 mg.
Vitamin B_6 (Pyridoxine HCl)	2 mg.
Vitamin B_{12} Crystalline	4 mcgm.
Calcium Pantothenate	20 mg.

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

Curbstone Consultation

Acutely Perforated Duodenal Ulcer

QUESTION: I have frequently been involved in discussions with colleagues as to the comparative merits of the management of acutely perforated duodenal ulcer by primary simple closure or emergency gastric resection vs. "conservative" or nonoperative treatment. Is there actually a place for conservative treatment considered alongside the time-honored operative methods for handling these cases? Is one justified in using conservative treatment in the patient who would be classed as a good surgical risk?

ANSWER: Proponents for nonoperative management stress the fact that in most reports conservative management has been reserved for those who refuse surgery or are too ill to survive any operative procedure. Naturally, in such cases the statistical results on behalf of conservative management are going to be poor. When a patient population group similar to those subjected to surgery are managed conservatively, the results are closely parallel.

Since very young and very old tolerate peritonitis poorly, it is probably best to treat these patients by simple closure as soon as they can be adequately prepared for surgery. If one elects to use the conservative method of management, he must thoroughly familiarize himself with the technique, follow the patient very closely, be able to recognize when this method is ineffective and be prepared to abandon it without delay in such cases.

Elimination of Drugs Causing Hepatitis

QUESTION: Would you recommend that drugs which occasionally cause hepatitis be eliminated?

ANSWER: I think that drugs that produce a viral hepatitis-like reaction should be eliminated, but those making cholestasis can be used if patients are watched carefully. Bilirubinuria should be an early sign to indicate withdrawal of therapy.

Fracture–Trauma Conference

Initial Evaluation of Soft Tissue Hand Injuries

When a penetrating wound or laceration of the hand or fingers is seen, several principles should be considered. The first is, of course, to avoid further damage to the already damaged structures; and the second is to evaluate carefully the extent of injury prior to the patient's going to the operating room and prior to the institution of anesthesia.

The wound about the hand is frequently bleeding quite profusely but no attempt should be made in the emergency room to apply clamps to the bleeding arteries or veins in order to control hemorrhage. There are very few occasions on which hemorrhage cannot be controlled simply by compression with sterile dressings and elevation of the hand. Probing about in a hand wound with poor light may lead to possible disaster, such as the clamping of a nerve. It is important to examine the wound itself for its size, especially in regard to any skin loss. The depth of the wound, however, should not be explored in the Emergency Room.

An x-ray of the injured hand should always be taken to rule out the presence of metallic foreign bodies or fractures.

It should be stated that there are very few tendon injuries which lend themselves to repair outside of the operating room under ideal conditions. Occasionally partial or complete division of extensor tendons in clean wounds can be repaired safely in the emergency room. Flexor tendons or tendon injuries in the fingers should be cared for only under the ideal conditions which exist in the operating room.

Even though the wound is covered, the hand can be examined to evaluate the extent of injuries to tendons and nerves. As much information should be gained as possible prior to the patient's going to the operating room to determine the extent of the injury, although it may be difficult to make a good evaluation of the injury in a young child or in an intoxicated patient.

Injuries to tendons can be detected in a variety of ways. The location of the wound, of course, would give some indication of the possible injuries which exist. The structures which lie in the area of the wound itself should also be considered injured unless one can prove them not to be by evaluation of their function. The status of the flexor tendons can often be quickly determined by merely observing the hand as it lies on the examining table. With lacerations of the tendons, a variation from the normal rest-

Continued

ing position of the hand will be seen. The resting position is one of slight flexion of all the finger joints with increasing amounts of flexion as one proceeds from the index to the little finger.

If one of the fingers is lying flat on the table while the others are flexed in the resting position, it is obvious that there has been some tendon injury.

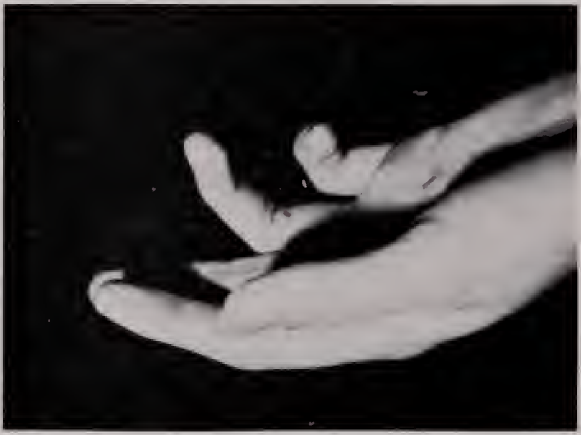

Fig. 1 — Tendon injury obvious from position of fingers.

Specific tests for function of the flexor tendons to the fingers can be carried out. With the middle joint of the finger stabilized, if the distal joint can be actively flexed, the profundus tendon is intact. With the adjoining fingers stabilized in extension, if the patient can actively flex the middle joint of the injured finger, the sublimis tendon is intact. The flexor pollicis longus, which flexes the interphalangeal joint of the thumb, can be tested by stabilizing the MP joint of the thumb.

Injuries to the extensor tendons can sometimes be deceiving unless certain anatomical principles are remembered. An injury to the extensor tendon over the distal joint of the finger will result in the well-known mallet or drop-finger deformity. An injury to the central slip of the extensor tendon proximal to the middle joint of the finger may not be detected immediately if one is not careful to be sure that active extension at each of the finger joints is intact. Extensor tendon injury at the metacarpophalangeal joint may not result in complete loss of finger extension because of the function of the fibers of the dorsal blood. The extensor pollicis

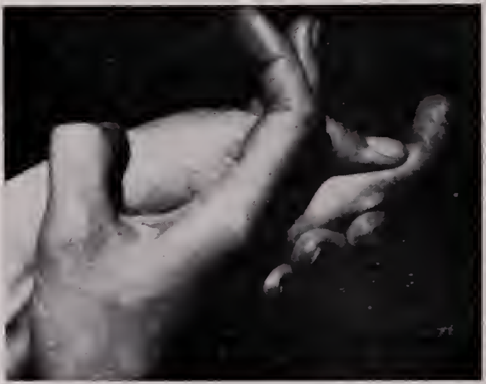

Fig. 2 — Test for profundus function.

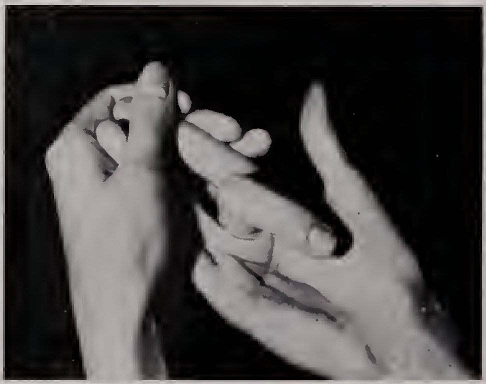

Fig. 3 — Test for sublimis tendon function.

longus tendon must be examined by checking the patient's ability to extend the interphalangeal joint of the thumb.

It should be remembered that partial division of a tendon might not be found by utilizing these methods of examination. This is something which often can only be noted at the time of repair of the wound.

Nerve function should be carefully checked during the initial evaluation of a hand injury. Sensation to light touch should be tested with a wisp of cotton, pain sensation with a pin. Motor function of intrinsic muscles also helps to localize a lesion.

In finger or palmar lacerations the digital nerves are vulnerable. If evidence of severance is noted on examination the nerve ends should be searched for and sutured. Failure to repair these can result in unsatisfactory finger function. If the patient has too much pain or is too excited to respond well it may be necessary to dissect out the nerve to determine if it is injured.

Injury to the radial nerve at the hand or wrist will not result in any loss of motor function. There will be a moderate loss of innervation of the skin over the dorsum of the hand and base of the thumb.

Median nerve function in the hand is generally in jeopardy when there has been a laceration on the volar aspect of the wrist. Whenever one sees a penetrating laceration at wrist level on the flexor surface, the median nerve should be considered lacerated unless it can be proven to be functioning. The chief motor function of the median nerve in the palm is, of course, function of the opponens mechanism of the thumb. Adequate opposition of the thumb is manifested if the patient can actively oppose the pulp of the thumb to the pulp of the long finger. In addition, active function of the abductor pollicis brevis can be checked, for this muscle is almost always (98%) innervated by the median nerve. Skin innervation by the median nerve should be tested; this area involves the volar surfaces of the index and long fingers, and half of the ring finger, along with the radial two thirds of the palm and the flexor surface of the thumb.

Lacerations toward the ulnar side of the wrist or a long laceration involving the entire wrist, should alert one to an ulnar nerve lesion. Motor function of the ulnar nerve can be tested in a variety of ways. One useful test involves evaluating abduction of the long finger, toward both the radial and the ulnar side. This should be done with the palm flat on the examining table to eliminate confusion with the function of the finger

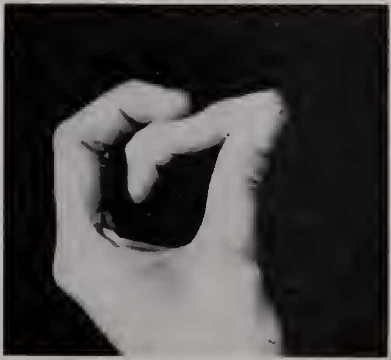

Fig. 4 — Median nerve (opposition).

Continued

extensors and flexors. The adductor pollicis, innervated by the ulnar nerve in 98% of patients, can be tested by Frommen's test. If the adductor pollicis is not functioning the patient uses the long thumb flexor to hold a card or paper between the thumb and the base of the index finger. Adductor pollicis function can also be demonstrated by the patient's ability to place the tip of the thumb against the base of the small finger. The sensory function of the ulnar nerve at the palm involves the ulnar half of the volar surface of the ring finger and the entire volar surface of the small finger, as well as the ulnar one third of the palm.

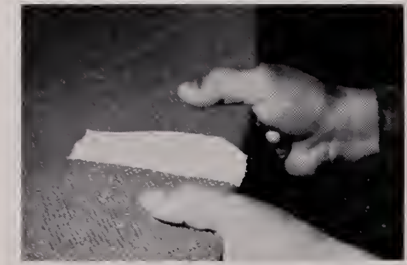

Fig. 5 — Frommen's test. Right thumb shows weakness of adductor.

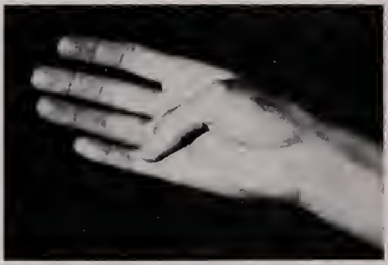

Fig. 6 — Test for adductor pollicis function (ulnar nerve).

Following the evaluation of the extent of the injuries, the patient should then be transferred to the operating room where the remainder of the evaluation is done after anesthesia has been begun. Inspection of the extent of injuries should be made along with and following the irrigation and debridement of the wound.

If the physician in charge of the initial management of the case finds that there is evidence of severe nerve or tendon damage, and he does not feel that he wants to take responsibility for the primary repair of the injured structures, the wound can very nicely be handled by simple cleansing and closure of the skin. Repair of deep structures which are injured can be done at a later date after the laceration has healed.

Joseph M. Tambornino, M.D.
Minneapolis, Minnesota

Overcoming Obstacles

Lincoln is reported to have said: "Some men are like the stump the old farmer had in his field — too hard to uproot, too knotty to split, and too wet and soggy to burn." His neighbors asked him what he did about it.

"Well, now, boys," he answered, "I just plowed around it."

Blessed is the man who, having nothing to say, abstains from giving us wordy evidence of the fact. — George Eliot

What we do in college is to get over our little-mindedness. — Robert Frost

Tumor Conference

Squamous Cell Carcinoma of the Parotid Gland

Malignant lesions of the parotid gland represent 20 to 35 per cent of all parotid tumors.[1] The following case report is presented because it represents a relatively rare tumor and especially because the approach to therapy stimulated considerable discussion at Miller Hospital Surgical Grand Rounds, and hopefully will interest others.

Case Report

A 58-year-old man was first seen on May 20, 1965, because of a lump in front of the right ear. This was noticed by the patient two and a half to three months previously, and shortly thereafter he noticed difficulty completely closing his right eye and weakness and drooping on the right side of his face. He admitted to some tingling sensation on the right cheek. There was an apparent drooping of the right side of the mouth but no limitation of opening. There was a 2.5 centimeter, nontender, slightly mobile, firm mass anterior to the ear, unattached to the overlying normal appearing skin. Closure of the right eye was possible, but the right facial muscles were generally paretic. Cervical lymphadenopathy was not apparent. The rest of the physical examination was compatible with his age.

X rays of the right parotid area and chest were normal. Laboratory tests were within normal limits.

On May 25, 1965, under general anesthesia, an incision was made over the mass anterior to the right ear, and an incisional biopsy was obtained. Two days later, after a definitive diagnosis of squamous cell carcinoma was confirmed, a radical parotidectomy with sacrifice of the facial nerve, a portion of the right masseter muscle, and a radical neck resection were accomplished. An ellipse of skin surrounding the previous incision with a wide margin was included in the specimen. A free nerve graft, utilizing the greater auricular nerve, was accomplished. The tumor involved the deep lobe of the parotid gland as well as a portion of the right masseter muscle. X-ray therapy was not advised because a good margin of normal tissue was removed surrounding the tumor and lymph node metastasis was not found. The postoperative course was uneventful.

Discussion

Squamous cell carcinoma of the salivary gland is a tumor of high grade histologic and clinical malignancy.[2] It comprised 0.5 per cent of the total and 3 per cent of the malignant parotid tumors in one series.[1] In this same series the three-year recurrence rate in patients with the more highly malignant tumors of the parotid gland was 73 per cent. The five-year survival rate for squamous cell carcinoma of the parotid reported by Arthur G. James in the *Cancer Prognosis Manual* was 19.2 per cent.[3]

Continued

The approach used in this case stimulated considerable discussion, as mentioned previously, since it involved deliberate incision into the tumor, and then delay awaiting permanent sections and examinations by the pathologist. Some felt that with obvious involvement of the facial nerve, resection of the parotid gland and those portions of the facial nerve involved with tumor could be accomplished without definitive pathological confirmation. Another point of discussion centered around the need for awaiting permanent section before planning the operation. Most all agreed a radical neck resection should be part of the therapy, but whether it was done at the same sitting or at a later date was a moot point. It was the feeling of those concerned directly with the care of the patient that better treatment could be accomplished by knowing beforehand the nature of the tumor. The Head and Neck Clinic at Memorial Hospital found that 36 per cent of all patients admitted for treatment of parotid tumors have had one or more previous operations for attempted removal of the growths.[4] It is apparent that at least some of these failures are the result of a poorly planned and hastily conceived operation. Frozen sections of parotid tumors are not always conclusive.[5] Needle biopsy has been advocated in some cases of "malignancies of the parotid clinically diagnosed to substantiate the diagnosis histologically in order to facilitate and plan the proposed operation."[6] Although it has been stated that paralysis had not been noted in the presence of benign tumors,[5] others have stated that infiltration of the nerve is sometimes found with nonmalignant growths,[6] thereby discounting the fact that just because paresis or paralysis is present the lesion is malignant. It seems reasonable that incisional biopsy with subsequent radical removal of the biopsy site, entire tumor, and contents of a radical neck resection offers less chance for spread of tumor than open biopsy at the time of the definitive procedure. In writing about retromandibular parotid tumors, Morfit has stated that the first hint of malignant tumor came only after the mass had been surgically exposed and removal was being attempted.[7] It is probable that many malignant tumors that are not retromandibular in origin are discovered in a similar manner and may account for at least a portion of the failures in therapy.

Summary and Conclusions

A case of squamous cell carcinoma of the parotid is presented, and a method of surgical treatment discussed. A well planned operation after a definitive diagnosis may be helpful in increasing the survival of patients with malignant parotid tumors.

Neuro-Pediatrics Conference

Cerebral Dysfunction Following Diabetic Acidosis and Coma*

Dr. Robert Bugenstein:**

A four-year-old boy, suffering from diabetes mellitus and mental retardation, was referred to the University of Minnesota Hospitals for further evaluation. He had been followed in the Oxboro Clinic since birth, where he received his routine immunizations. At fourteen months of age he was hospitalized for severe dehydration and coma and discovered to have diabetes mellitus. During his hospital stay he had one or two convulsions which were felt to be due to hypertonic dehydration associated with the diabetic coma. Following discharge he was placed on a 1200-calorie diet and appeared fairly normal except for a paralysis of the left hand and an "off-and-on" twitch in the left eye. Over a period of several months, however, the function in his left hand returned to normal.

At 17 months of age he was able to walk around furniture. At 18 months he had a prolonged grand-mal seizure which did not respond to intravenous glucose but did respond to intramuscular phenobarbital. He was hospitalized, and an electroencephalogram revealed moderate to marked spike-and-wave paroxysmal abnormality focal in the right frontal region. He was placed on Dilantin at this time.

By 20 months of age he was able to walk fairly well and used both hands adequately. At two years of age he was on nine units of regular insulin and twenty-six units of NPH insulin. He was not able to talk but was able to feed himself. When he was 29 months of age, his mother noted that he was having akinetic seizures and was developing hypertrichosis on his arms and legs and some fat atrophy on the upper arms and thighs. Another electroencephalogram was done and interpreted as showing a marked abnormality with continuous spike-wave activities.

At three years of age he was still being maintained on Dilantin, three-a-day and phenobarbital, ½ grain three-a-day; but as the phenobarbital

Continued

caused hyperactivity, it was discontinued. His growth rate as measured by his height and weight was normal for his age. He was able to say only "ma-ma" and "da-da." He was still being fed by his mother and given a bottle from which to drink milk. His development appeared to be even more grossly retarded than before, and there was no creative pattern in his play. When he was three and a half years old his mother noted that he had a habit of banging his head on furniture or on the floor. He spoke no words but did understand directions.

On his last visit, at age four, he showed increasing hyperactivity and a greater discrepancy between his chronological age and his developmental level which was approximately 15 to 17 months. There was some moderate atopic eczema in the anticubital fossae, the wrist and the backs of his knees. He was started on Desoxyn in an attempt to control his hyperactivity.

Both parents expressed an interest in having the patient seen at the University Hospitals. The mother, who tends to be a very tense individual, came in only periodically for checks with the patient. His diabetes has never been closely controlled, as an attempt has been made to keep him on the side of hyperglycemia in order to avoid any hypoglycemic attacks.

Dr. Sheldon Hess:*

The mother's presenting complaint at the Pediatric Clinic was that she wanted a neurologist and psychologist to look at the patient, explain the extent of brain damage, and also give a prognosis as to what his future development and capabilities might be. She seemed extremely nervous and somewhat hostile.

The patient was the product of a low forceps delivery. Some tremors and a high cry were noted on the first day of life. He was discharged from the hospital on the fourth day in apparently good condition. Eczema was observed at two months of age, which improved with the removal of milk. Polyuria and poor appetite were evident several days before the onset of diabetic coma.

A review of the hospital records at St. Barnabas showed that on admission at 14 months of age he had sunken eyes, was very irritable, and had a weak cry. His blood glucose initially was 1,300; BUN, 37 mgm.% and CO_2-3 meq./ml. The day after admission he had a grand-mal convulsion, and his prognosis was considered very grave; his pupils were dilated and reacted poorly to light. Blood sugars drawn during his hospitalization varied between 72 to 256 milligrams per cent. His electrolytes on the eighth day of admission showed a sodium of 152 meq./ml., and chloride of 113 meq./ml.

Physical examination at the initial University visit showed a non-co-operative, hyperactive child of normal height and weight. There were no significant physical findings and his neurological examination was normal.

Dr. Frank Wright:**

On examination the patient revealed extreme hyperactivity, and no positive neurological signs were noted. His head size of 48 cm. is significantly subnormal, thus correlating with a lack of adequate brain growth and development. Examination of the fundi revealed no vascular changes and no cataracts.

---

*Student Physician, University of Minnesota Hospitals.

**Assistant Professor, Pediatrics and Neurology, University of Minnesota Hospitals.

An electroencephalogram showed a moderately to markedly abnormal record, with depression of activity in the right hemisphere, paradoxical slowing in the occipital and temporal regions, paroxysmal irregular polyspikes and slow waves in the right temporal frontal region, and paroxysmal spike activities in the right frontopolar region. The record was compatible with possible atrophy on the right with irritative lesions.

The patient should continue on his anticonvulsant medications indefinitely. In view of his past history the Dilantin should be maintained. Phenobarbital is not indicated, since he had increased hyperactivity on this medication. Equinal has been added to the therapeutic regime in an attempt to calm the patient; however, this has not been satisfactory. Phenothiazid compounds have been tried; but one runs the risk of potentiating a seizure disorder with these drugs.

Dr. Robert ten Bensel:*

It is well known that diabetic acidosis and coma are seen more frequently in younger patients; however, most of the mortality from diabetic acidosis occurs in the elderly patient and is complicated by other disease, particularly arteriosclerotic heart disease. There have been other studies[1] done, showing that the mortality and morbidity of diabetic acidosis is related to the extent of unconsciousness, circulatory collapse, and the degree of hypoglycemia and azotemia, but not to the total CO_2 content. Other authors have commented that in diabetic acidosis the possibility of insulin shock may be one of the major complications leading to cerebral dysfunction. It has been shown that with hypoglycemia there is decreased oxygen consumption by the brain, with three to five per second delta-wave activity on the electroencephalogram.[2] Pathologically, in the brain, there may be cerebral edema, petechiae over the convexity of the cortex nerve-cell alteration, diffuse, focal glial proliferations and areas of demylinization.[3] Gardner[4] states that in hypoglycemia, brain glycogen is decreased, and animal studies have shown that the high centers of the cortex are first affected, followed by the upper brain stem and finally the medulla. Transient hemiplegia and aphasia have been noted to follow diabetic acidosis; however, these usually clear up in a matter of a few days to months.[1] Convulsive disorders, emotional disturbance, and intellectual deterioration have also been noted following diabetic acidosis; but these complications are felt to be exceedingly rare.

Dr. Wright:

The pathological changes in hypernatremia are very similar to those seen in hypoglycemia with cerebral edema: pial hemorrhages which may progress to actual subdural hemorrhages. It is certainly possible that a combination of factors may have been playing a role at the time of this patient's diabetic acidosis and coma. Whatever the cause, he suffered a severe injury and, from the lack of progression since that episode, one would expect little in the way of return in function at this point. His prognosis for any further improvement is very poor.

Dr. Harold Ireton:**

The results of intelligence and related tests indicate severe mental re-

tardation. On the Cattell Infant Intelligence Scale his mental age was 11 months: an I.Q. of 23. On the Vineland Social Maturity Scale his mental-age rating was 16 months (Social Quotient-33). In the testing situation, he was co-operative and quite testable and did not display any serious negative emotional reactions. He reportedly manifests immature behavior in stress situations. The parents' Minnesota Multiphasic Personality Inventories were normal. One other approach to the problem of hyperactivity might consist of helping the parents to handle the stressful situations that arise in the home.

Mrs. Mary Cordingley:*

This mother was a rather quiet, soft-spoken woman, appearing to be very understanding with this extremely hyperactive child. She was somewhat depressed in discussing her family and tended to be self-condemnatory. Her initial attitude was that she was able to take care of this child in the home situation; however, over the past several days, she has become extremely tense and has started condemning herself for inability to handle him. She supervises the daily wild behavior of banging doors, jumping on furniture, playing in the toilet, and dumping drawers and contents. She does not favor placement, because she is particularly aware of the limited nursing staff in state institutions and doubts that this child could get the nursing care he needs.

The father is frank about his inability to accept his child's wild behavior; he was very tense regarding the situation and was willing to discuss placement. At the same time he was understanding and considerate of his wife's feelings and has not pushed the issue with her. He did go to the Hennepin County Welfare Department to initiate arranging for guardianship and placement, but his wife was not included in the initial visit. The Hennepin County Welfare Department is now arranging an interview with him in the near future. Mr. Eddy of the Welfare Department is well acquainted with the facilities which would care for the patient's physical needs adequately. The possibilities at the present time include a trial period at Minneapolis Association of Retarded Children Day Care Center.

The family constellation is made up of three other children: boys aged 21 and 19, and a girl aged 15. Both parents expressed disappointment in the scholastic attainment of their children. The 15-year-old girl is a very shy, withdrawn individual, and this concerns both the parents. She is not doing too well in school, and one canont help but wonder what influence this young retarded child might have on the total adjustment of the family.

In a telephone conversation on March 23rd the mother seemed very distraught and had begun to take the patient's Equinal; since then, she has stopped doing so. Certainly more immediate support is needed for the family. At the present time the parents have planned to affiliate with the Minneapolis Association of Retarded Children to get help in adjusting to the patient's retardation and to provide some interests outside the home.

Dr. Bugenstein:

The mother has probably become more aware of the increasing discrepancy between the patient's chronological and developmental age. She seems to be very protecting of the child and has not been willing to discuss these problems openly with him.

---

*Social Worker, University of Minnesota Hospitals.

Dr. Wright:

Possible foster-home placement might be more satisfactory at the present time to allow the family to adjust to a permanent placement situation.

Final Recommendations of the Conference

1. A conference will be held with the parents regarding their son. At this conference, Dr. Wright, Dr. Hess and Mrs. Cordingley will inform the parents of the results of the conference. Hopefully, Mr. Eddy will be able to attend this meeting and attempt to work out possible foster-home arrangements in the immediate future.
2. The parents are encouraged to continue with their state guardianship plans; these should be undertaken promptly, since the institutional waiting lists have a long waiting period.
3. The patient will be discharged from the clinic and returned to the care of Dr. Bugenstein, who will maintain primary medical responsibility for the child.
4. Since a disrupted family situation is present, the possibility of referral to Family and Children's Service should also be considered. This will be discussed at the meeting with the parents.

Robert ten Bensel, M.D.

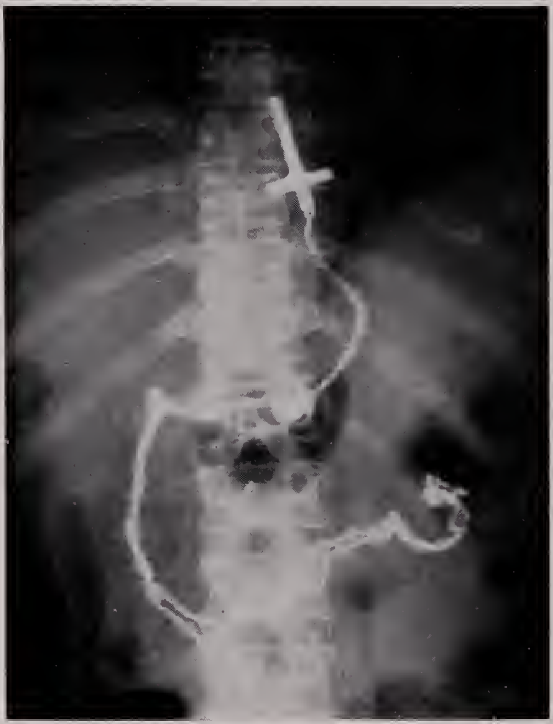
WHAT WOULD YOU HAVE DONE?

A 45-year-old white housewife came to the Hennepin County General Hospital with a history of increasing painless jaundice of three weeks' duration. She had been drinking at least a quart of wine daily for the preceding ten years. The physical examination and laboratory studies were compatible with a diagnosis of alcoholic-nutritional hepatic cirrhosis with ascites.

During her hospitalization the jaundice increased and she became confused, lethargic, oliguric and azotemic. Treatment consisted of the usual supportive measures, steroids and diuretics. With this regimen she began to improve.

After two months of hospitalization she developed an acute paranoid psychotic reaction. She put a rosary in her mouth "to keep it from being stolen." She then said that she swallowed it and the following x-ray was obtained. What would you have done? (See page 1369)



Right or Left?

Position or direction is often an important matter in Pliny's, as in magic, ceremonial. It perhaps comes out most frequently in his specification of right or left. An aching tooth should be scarified with the left eye-tooth of a dog; a spider which is placed with oil in the ear should be caught with the left hand; epilepsy may be cured if a virgin touches the sufferer with her right thumb; for ophthalmia of the right eye suspend the right eye of a frog from the patient's neck, and the left eye for the left eye; for lumbago tear off an eagle's feet away from the joint, and use the right foot for the right side and the left for pain in the left side.*

Child Psychiatry

Recognition of the Abnormal School Child*

Recent surveys of school populations in various cities reveal that seven to twelve per cent of school age children have emotional problems which deserve professional help.[1] This increasing recognition of the extent of emotional disturbance in children reflects the greater awareness of teachers regarding problem behavior and the addition of trained counselors and special service personnel to school staffs. The marked rise in the public mental hospital population of the ten to fourteen-year age group in recent years as compared to a decrease in the adult hospital population also indicates the greater awareness of children's problems.

Children's abnormal behavior, if not indicative of a physical problem, is often a symptom of underlying emotional conflict. The behavioral signs usually appear early in a minor form and, if unheeded, progress to more noticeable or more pervasive symptoms, all of which represent the child's "cry for help."

In evaluating any child's behavior or emotional problems, we should look beyond the presenting symptoms to the total child and his broad adjustment. Often this includes a consideration of his family and how they are functioning in their individual inter-relationships and also as a group. The physician who knows and treats the whole family and who has been in the home repeatedly, has a most useful insight to contribute which may not otherwise be available.

Infantile Habit Patterns

Emotional and behavioral problems in children often go unnoticed during the first five years while the child is primarily at home; but when the child enters school, he is for the first time seen in comparison to his peer group by a school staff who have a neutral outlook. At this point behavior traits may take on new meaning.

Children begin school at about age five when they are emotionally through the early developmental years and are ready to direct their energy primarily toward intellectual learning and academic competition. Some children, however, still retain infantile habit patterns which suggest prolonged emotional immaturity. These include thumb-sucking, rocking back and forth, extreme dependency and shyness, toilet-training problems, inability to tolerate even the mild competition of the group, or inability to stay in their seat in class. These are children who did not receive sufficient gratification of infantile emotional needs, or whose needs were stronger than usual and not as easily satisfied. Their infantile patterns may interfere with their ability to adjust to the classroom situation and to learn in school. If such children are otherwise happy, relaxed, and socially well adjusted outside the school setting, their persisting habits may not be of specific concern and will disappear with maturation. Angry, punitive parental attention does not help the child to grow out of these habits.

*Presented May 18, 1965, Minnesota State Medical Association Annual Meeting in Minneapolis, Minnesota.

Continued

If these infantile habit patterns persist, they suggest deeper emotional problems and should be further evaluated.

Hyperactive Behavior

Hyperactive children quickly receive attention from the school. These children present a picture of impulsive, restless behavior with a short attention span, poor concentration ability and impaired visual-motor coordination. They are easily distracted. They frequently disrupt the class and upset the teacher by their continual talking and random physical activity. The hyperactive behavior syndrome is seen more in boys and often is first noticed when the youngster is seven or eight years old. If hostile-aggressive or destructive behavior is also present, the child may be so difficult that he cannot be tolerated in the classroom situation. Hyperactive children usually present more of a problem in school where activity and the large class group overstimulate them beyond the tolerance of their inner controls. In quiet surroundings or in a one-to-one relationship they are not so upset, and they can play and learn more satisfactorily. They often receive help sooner than the quiet, introverted child who may be much more disturbed basically but does not attract so much notice.

Hyperactive behavior is not infrequently seen in children with demonstrable neurological findings and a specific history of a brain-damaging illness; then a causal relationship is likely. Retarded neurophysiologic maturation, which can be inherent or a result of negative emotional experiences in infancy, may produce the picture of the hyperactive syndrome with diffuse undefined cerebral dysfunction. As some abnormality in the electroencephalogram is found in approximately one third of all children, this test itself is not diagnostic for brain damage. Moreover, the diagnosis of brain damage does not invariably mean the problem is irreversible and untreatable. The hyperactive behavior syndrome has often been erroneously equated with organic brain damage. Such false equation may minimize attention to emotional problems which can cause identical behavior symptoms.

Identical hyperactive behavior is observed in children who have suffered gross deprivation of maternal affection in infancy. This, in the past, was particularly observed in children reared in orphanages and other such large institutions with inadequate adult staffing. This degree of severe emotional neglect is seen in some families where it produces the hyperactive pattern with poorly internalized impulse control and a persistent random seeking for unfulfilled emotional gratification. The hyperactive pattern may also result when a child is unwanted or a mother does not have the emotional capacity to adequately provide affectional nourishment and support to the infant. Similar behavior is shown by children whose parents unconsciously expect them to be overactive, uncontrolled and difficult to handle because of the parents' own early experiences. In such instances a careful evaluation of the inter-relationship between the child and both his parents is essential for adequate diagnostic understanding.

Whatever the cause, hyperactive behavior patterns produce frustration in these children because of their inability to conform or achieve up to their potential. Superimposed emotional conflict results, adding to the total problem.

The hyperactive behavior syndrome is one of few conditions in child psychiatry where one occasionally obtains a sudden dramatic response to medication. Moderately strong tranquilizers, such as Mellaril® and Librium,® are often effective. Sedatives, particularly phenobarbital, will quite often increase activity, while stimulants such as dextroamphetamine or Ritalin paradoxically have a calming effect. Unfortunately, the response is often not a lasting one and in a period of two to six months, the child may again present the same problems. Anticonvulsant medication may be effective if the child has specific organic cerebral disease.

Hyperactive behavior often disappears as the child enters adolescence. This emphasizes the importance of these children having help with the frustrating consequences of their problem so that they may enter adolescence with sufficient emotional health and optimism to make the best use of subsequent experiences.

Related to the hyperactive child we see children who are not so much hyperactive as constantly restless, uneasy and impatient, and who may be described by the parents as tense, high strung, jittery or nervous. These children may have tension-relieving habits which seem to be most annoying to adults, especially parents. Such habits include tics of the face, head, eyes, and throat. Sometimes open masturbation is observed in these children or they display rhythmic, tension-relieving behavior which is masturbatory-equivalent. These children are often found to be reacting to an excess of parental control, criticism, reminding and nagging. They are constantly in movement as if to please their parents by the amount of activity rather than the quality of its direction as well as to relieve their own tension. These children are frequently resented by parents or have proven to be a disappointment to them. The parents' attitudes are conveyed to the children by excessive negative criticism.

Neurotic Learning Problems

Many children have learning problems which arise from neurotic inhibition or suppression of curiosity. Such problems are often serious as far as their influence on the child's future academic life and his total productive capacity as an adult are concerned. Specific reading disability is such a problem, in which the youngster fails to acquire reading skills. If this is not detected and evaluated early so that remedial help can be given, the child soon finds himself hopelessly behind the rest of his class. So much of education is dependent on reading that before long there is little reward for him in any area in school. Specific reading disability may be related to an intense suppression of visual curiosity in the preschool period because of repeated admonitions from the parents not to be curious, investigate, or "get into things" as children normally do. Some children witness scenes so unpleasant that they prefer not to continue looking, and this may interfere with reading proficiency in school.

There also can be more general suppression of learning curiosity. This may be reflected by apathy toward school generally, even in the presence of superior intelligence. Such learning problems contribute strongly to a school drop-out problem. When such a youngster gravitates toward other scholastically unmotivated adolescents, this problem may contribute to delinquency.

Nonlearning may be the child's passive-aggressive way of defying his

Continued

parents' insistent demands that he study and learn so that they may be pleased with their own parental accomplishment. The strong positive relationship between parents and child which would motivate him to want to do well in school in order to please his parents is absent. The love and the positive feelings are lacking and the child primarily senses the impatient demand from his parents, which he is not willing to acceed to; hence he resists learning as a way of withholding affection from them.

A child may be aware of his parents' negative attitude about his school, teachers or about education. For the child exposed to these attitudes to be obedient and compliant, he must adopt the same negative attitudes for himself. Open or covert defiance of the school staff and academic progress may result. In such a situation, the attitudes of the parents need to be exposed and modified before the child can be expected to change. In such families the parents often subtly enjoy the child's defiance of school and the disturbance he creates there and, although they make conscious efforts to discipline him, the child is more responsive to their unconscious expectations of him. It becomes additionally confusing to the youngster when he finds his parents punish him for the very behavior which their underlying attitudes encourage him to display.

Another category of nonlearning includes the child who has been so completely overwhelmed by parental overindulgence and overprotection that he has not had an opportunity to learn to think and act independently. Children gradually acquire the ability to think for themselves, to use their initiative, to learn from experience and to take responsibility. If parents lose sight of the fact that their child is constantly maturing and do not transfer responsibility to him gradually, the child may fall into a pattern of passive withdrawal and avoidance of any initiative on his own behalf. This is a comfortable pattern for him since, by making no decisions, he does not have to take the responsibility for his own decisions. As these youngsters enter adolescence, their passive dependency may be so great as to preclude any further emotional growth or academic progress.

Neurotic Children

Anxious, neurotic children comprise another large group of children with emotional problems. Attacks of acute anxiety may occur in children at any age but are seen more frequently between ten and fifteen years of age.[2] The child who suffers acute anxiety episodes usually has a history of previous anxiety which may have been less pronounced and went unnoticed. The anxiety may reach hysterical proportions; an acute episode can be precipitated by almost any emotionally traumatizing experience. A death, illness, or accident in the family or even in the neighborhood may serve to bring underlying anxiety to the surface. Some anxiety arises out of the child's conflict about his own hostile destructive wishes toward those on whom he is dependent. Such a child may lose his appetite, experience nausea, vomiting, stomachaches, and headaches; he may have serious sleep disturbances and nightmares. His anxiety is often related to body function and expressed as a fear that his heart will stop, that he can't swallow, or that he will stop breathing. Death is often involved in his fears, as is being killed or kidnapped.

More commonly we see the child without acute episodes of anxiety but who shows persistent neurotic anxiety and is very fearful about certain situations. He is often frightened at night and resists going to bed. Some restriction of play activity is common because of fear. He doesn't like to go away from home to play. He is too anxious to spend a night at a friend's home or even with a relative and may become quite upset if the parents leave home and a babysitter comes. He may often be frightened by storms or the dark or have peculiar food fears or ritualistic anxieties about clothing. Obsessive-compulsive habit patterns are commonly seen in this group and represent efforts to bargain with the conscience in order to control inner fears.

Some anxiety, sleep disturbance, and phobic concern is normally observed at age six or seven, before the child enters the latency period of his emotional development. However, persistence of such symptoms to any degree becomes significant, particularly if the child's whole personality and energy are invested in the neurotic conflict. If the anxiety is considerable, it will affect the youngster's attitude at home, his adjustment to his siblings, his relationships with his playmates, and his performance in school. Allowing this neurotic anxiety to persist for any length of time permits it to become more deeply entrenched in the child's personality structure.

Tranquilizer medication is of relatively little value, although it may offer brief support and reassurance. In neurotic children anxiety is usually so pervasive that medication does not offer substantial relief. They do respond well to psychotherapy, however.

One specific neurotic problem which we see only in school children is "school phobia." However, it does not represent a phobia of school itself but an anxiety about separation from the parent.[3] In this problem a dependent child is unable to separate himself from a (often unconsciously) clinging parent each morning in order to go to school. The involved parent, usually the mother, does not really want the child to leave and communicates this to the child in various subtle ways. On the surface the parent makes obvious efforts to send the child to school and even punishes him harshly for not going as demanded. The problem first creates concern at about eight or nine years of age, although in retrospect one can see the beginning of the separation anxiety in kindergarten and the first grade. The affected child is often an only child in the family or the youngest, a timid, shy child who is passive and dependent on the parent. For the first year or two in school, the child is able to suppress his fear of leaving the protective home situation, but eventually, usually following an illness or a vacation which allows him to stay at home for a few weeks in a situation of happy dependency, the child becomes extremely reluctant to return to school. Characteristically, once he gets to school for the day and the parent leaves the scene, the youngster relaxes and is relatively comfortable. The next morning he presents the same anxiety, however. The intense fear is most noticed at the beginning of the week and immediately after a school vacation. Treatment of this problem involves concurrent treatment of the parents. These parents often reflect an emptiness in their own life which gives rise to their deep reluctance to let their child leave them to go to school and thus to grow up and away from them. Occasionally we see school-phobia reactions persisting into early adolescence. When this occurs it is indicative of a deeper disturbance. A severe and often incapacitating hostile-dependent relationship may then exist between the adolescent

Continued

and involved parent. Some older children with school phobia become extremely withdrawn and progress to a schizophrenic illness in adolescence.

Depression

More depression exists in children than is often recognized. Depression may be disguised by a multiplicity of psychosomatic complaints or by a withdrawal into an apathetic adjustment which goes unnoticed. Such children feel empty, discouraged, and often entertain thoughts of dying; occasionally these are acted out suicidally in what appear to be accidental childhood deaths. In early adolescence the depression is less masked and suicide is one of the more common causes of death. There is an element of strong hostility in adolescents who attempt suicide. The anger is usually aimed at the parents, or it may be diffusely directed against authority in general. These youngsters are literally angry enough to kill, and whether they kill themself or the hated parent may be a close decision. Occasionally adolescents express their suicidal thinking or other unhappy preoccupations in themes they write at school. Teachers have become quite perceptive in picking up the significance of the content in such writings. Any real suicide threat or attempt by a child or adolescent should not be ignored, although some of the threats are impulsive and do not indicate that the teenager is self-destructive. Hospitalization, however, is usually not indicated for these youngsters. When confined they lose what little freedom they had and their resentment is mobilized against the very adult authority they are fighting. This provokes more anger and also gives them a new focus for their anger rather than an opportunity to work through their original hostility and conflict.

Delinquency

Delinquent behavior in the preadolescent and in the adolescent is another broad area which the physician should recognize as often being an expression of underlying feelings. In a child from a socially deprived home in which he is presented constantly with delinquent patterns or a delinquent neighborhood environment, antisocial acting-out behavior may occur as a rather natural consequence of external influences. Such a child may present a social problem in the community and still not have any specific psychiatric or personality problem himself. However, predelinquent or delinquent behavior in a child from a better socioeconomic background and a cohesive family should alert one that the child may be trying to express something by his behavior, such as his unhappiness or discomfort under pressures in his situation. His delinquency may be a covert attack against his parents and what they stand for. Sometimes it is a poorly concealed effort to get himself removed from his home where he feels the demands are more than he can tolerate. True psychopathic or sociopathic character disorders with absence of conscience or super-ego development are very infrequent in adolescents, although the angry, indifferent or defiant facade behind which many delinquents hide their vulnerable, real feelings may often resemble the character structure of the psychopath.

Psychotic Disturbances

Withdrawal into fantasy is quite common in children and adolescents, even to an extent that would be considered psychotic in adults. A frank psychosis is infrequent in childhood but may occur. Infantile autism describes a very early psychotic disturbance in which a young child exists in his own world of fantasy and relates to people as if they were inanimate objects. An acute psychotic illness is rare in childhood and is suggestive of a toxic or organic etiology. Childhood schizophrenia may develop as a gradual, progressive process. With the onset of adolescence a weakening of ego strength occurs concurrent with the internal and social pressures accompanying puberty. If the ego is not strong enough to contain the instinctual drives and impulses, decompensation into a schizophrenic illness may take place. This happens particularly in the previously shy, withdrawn, oversensitive youngster. The adolescent who has used obsessive-compulsive defense mechanisms extensively may also experience a schizophrenic psychosis as his defenses break down. The diagnosis of schizophrenia in adolescence is more difficult to establish than in adults. Adolescents are frequently diagnosed incorrectly as schizophrenic because of behavior which, although at times associated with schizophrenia, may also be characteristically adolescent.[4]

School's Role

The school setting offers an excellent observation and detection opportunity for the early recognition of children with emotional disturbances and behavior problems. Schools at present, however, can do little more than observe and occasionally offer some diagnostic screening by psychological tests. Such test results, including measurement of the I.Q. and academic achievement, are usually available to the physician and can prove most helpful in his evaluation of a child's emotional status. When school personnel encounter abnormal behavior in children, they often need the physician's help in effecting an adequate referral to the child psychiatrist or other appropriate community resource. Effective evaluation and treatment of the child with emotional conflict often involve treatment of one or both parents.

accurate—comparable to the older standard intradermal tests
practical—can be administered by nurses under physician supervision
convenient—no refrigeration or other storage precautions
economical—stable for 2 years, self-contained disposable unit

Side effects are possible but very rare: vesiculation, ulceration or necrosis at test site. Contraindications, none; but use with caution in active tuberculosis. *Available* as the new individually-capped unit, boxes of 5, or in cartons of 25.

Athletic Injuries

Evaluation and Immediate Treatment of Soft Tissue Knee Injuries Sustained in Athletics*

The knee is probably the most vulnerable of all the joints to athletic injury. Its anatomy is such that stability is present only because of the ligamentous structures and quadriceps mechanism. It is a flat hinge joint with a sliding component as the tibia flexes and extends on the femur. It lacks the ball-and-socket construction of the hip and the mortise of the ankle from which to gain its stability. Furthermore, it is vulnerable because of the length of the lever arms of the bones which articulate to form the knee joint.

Contusion, torsion, and angulatory strain are the forces which result in injury to the knee joint. Pain and swelling (effusion) are undoubtedly the most frequent symptom and sign of knee-joint trouble; and the usual etiology is traumatic synovitis secondary to contusion, twisting, or forced angulation. Once again, it is the team physician seeing the player immediately after injury who has the best opportunity to make an accurate diagnosis of the injury and of its severity.

Diagnosis

The reaction of the athlete to his injury immediately after it has happened is often an elucidating sign as to how seriously he has been hurt. If he has full range of motion of the knee and can bear weight without persistent pain, chances are that his recovery will be rapid without residual disability. On the other hand, if the knee is locked or unstable, or if the pain is "unbearable," that athlete may be in for a long period of rehabilitation, including possible surgery, with a high probability of permanent disability.

Physical examination of the knee at the scene of the injury should include the testing of the lateral stability, both with the knee fully extended and with the knee flexed 30 degrees. Instability with the knee in full extension indicates rupture of at least one of the cruciate ligaments as well as the collateral ligament involved; instability only at 30 degrees indicates rupture of the collateral ligament in question. The anterior "drawer sign" is a more specific test for the anterior cruciate, and the posterior "drawer sign" for the posterior cruciate ligament. The test consists merely of either pulling the tibia anteriorly on the femur, or pushing it posteriorly; excessive motion means ruptured ligament.

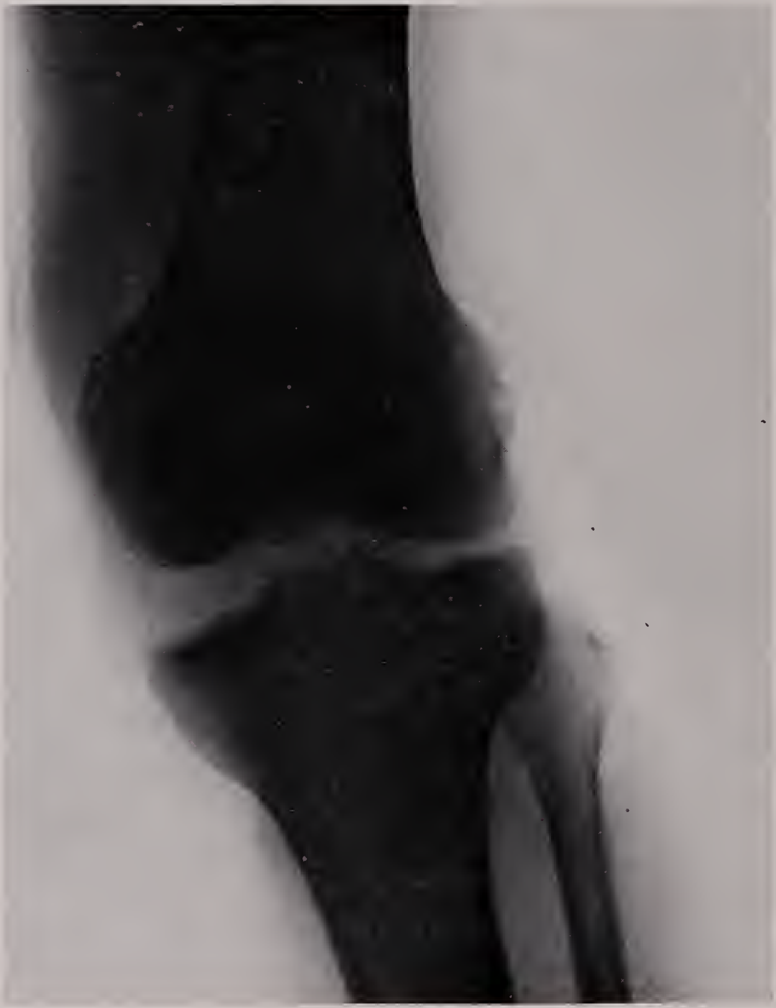
---

*See Minnesota Med 48:1173 for first in this series. Sponsored by Minnesota Committee on Trauma of the American College of Surgeons.

Continued

A locked knee suggests strongly the possibility of a torn meniscus. The medial meniscus is much more apt to be injured than the lateral because of its configuration and because of its intimate attachment to the medial collateral ligament. With a sprain of the medial collateral ligament, the medial meniscus is also often torn.

X-rays should be taken in three views: AP, AP tunnel view, and lateral. Stress films are indicated to confirm and record ligamentous laxity or rupture (see Figure).



Valgus stress film with knee flexed 30 degrees. Consistent with rupture of medial collateral ligament.

Treatment

If a severe injury to any of the ligaments or to either of the menisci has occurred, hemarthrosis and effusion usually follow immediately. The quicker a bulky pressure dressing is applied, the less bleeding and effusion there will be. Aspiration of the joint is indicated both as a diagnostic aid and as a way of relieving discomfort; it should be done under strictly aseptic technique. If there is hemarthrosis, a tear of a ligament or mensicus has most probably occurred. If there are fat globules in the aspirate, a fracture has most probably been sustained. Decreasing the intra-articular pressure definitely affords relief of pain. Pressure dressing, elevation, and ice packing are deterrents to reaccumulation of blood and joint fluid. Should hemarthrosis reform, multiple aspirations are warranted in order to avoid the complications of protracted resorption of the blood, which leads to synovial reaction, formation of fibrin deposits, and adhesions.

In the case where a sprain has occurred and there is a possibility of internal derangement as well, a cylinder cast for 2½ to 3 weeks is indicated. This will allow soft tissue healing to take place with the knee immobilized, and the patient will be comfortable. He may bear full weight without fear of the knee hurting or buckling. Then, after motion has been regained following removal of the cast, further evaluation of the status of the menisci can be done. If the patient has either a locked knee or rupture of ligaments, surgical consultation concerning the advisability of meniscectomy and /or early surgical repair of the ligaments is certainly indicated.

Rehabilitation

An athlete should not be allowed to return to participation until there is no longer effusion present. He may be able to participate, but he will in most instances do damage to his knee if he engages in athletic activity while there is still effusion present. Rehabilitation consists of isometric progressive resistance exercises of the quadriceps, guarded and progressive weight bearing with crutches, and active range of motion exercises until full range of motion is achieved. The quadriceps of the injured knee should be at least as strong as — and preferably stronger than — those of the normal knee. If ligaments have been severely strained or torn, the knee should probably be protected with criss-cross taping during future competition.

Minneapolis, Minnesota

Imhotep

Imhotep (2980-2950) was an Egyptian priest and philosopher during the reign of Pharaoh Zoser. As priest familiar with magic and as philosopher conversant with natural law and physics, he was also, by extension, a physician, since in ancient civilizations magic and medicine were inseparable. Furthermore, 'physician' derives from 'physicien': a natural philosopher, an experimentalist in physics.

Because of Imhotep's phenomenal cures, shrines and temples rose in his honor, to which the ailing and afflicted pilgrimaged for his intercession. So exalted did his figure become that after his death, he was deified as the son of the god Ptah — one of only two Egyptian mortals so invested posthumously with divine paternity. The myth of immaculate conception has been indigenous to several ancient cultures; Christianity has not been the only institution to incorporate it into its doctrine.

For centuries Imhotep's shrines multiplied and continued as meccas, and his temples proliferated and flourished as medical centers. The most magnificent of these latter, that at Saqqara, was called the Asclepieium, since Imhotep was regarded as the Egyptian counterpart of the Greek Aesculapius. The Egyptian demigod physician is represented as a seated, shaven priest holding an open scroll on his knees.

Grand Rounds

Thrombolytic Therapy*

The development of new means to control disease processes has resulted in a great increase in the number of persons in the older age groups. These older people have a higher incidence of diseases which cause or are associated with thrombotic disorders. Surgical treatment of these thrombotic complications is frequently not possible. Anticoagulants, while preventing in many cases further thrombosis, probably have little benefit in restoring circulation to the ischemic area. Anticoagulants are capable of preventing propagation of a thrombus once formed but cannot lyse the newly formed clot. Thus, the development of usable thrombolytic agents would be a major advance in the therapy of thrombo-embolic disease.

History

The term "fibrinolysis" was introduced for the first time in 1893 by Dastre, who used it to describe his observation that the blood of people who died a sudden death did not clot. It was mostly a descriptive concept until 1933, when Tillett stimulated further experimental investigation with his discovery that clots of human plasma would dissolve rapidly in the presence of filtrates of certain strains of hemolytic streptococci.[1] The substance in these filtrates has subsequently been identified as streptokinase (SK). In 1952, Johnson and Tillett first reported that infusion of high doses of streptokinase in rabbits produced partial lysis of 50 per cent of thrombi experimentally produced in ear veins.[2] In a series of experiments on animals Cliffton produced complete lysis of experimental thrombi in several different veins of a variety of animals without side effects.[2] The first reported experience of trials with plasmin infusion in humans was published in 1956.

Mechanisms

An understanding of the basic mechanisms of fibrin formation and

---

*Presented as a Medical Grand Rounds at Mt. Sinai Hospital, Minneapolis, November 10, 1964.

Continued

fibrinolysis is important to the understanding of thrombolytic therapy. The whole process is a dynamic one, continually in action at numerous sites in the vascular system where stress and trauma occur. If the clots formed at these sites were not dissolved, life could not go on. The first three stages of the clotting mechanism are well known; but the fourth stage, that of fibrinolysis, has not received as much attention.[3,4]

Although the processes of coagulation and fibrinolysis are antagonistic, there are similarities in their mechanisms.[1] A proteolytic enzyme is produced by each system (thrombin and plasmin). Thrombin splits off a small particle (fibrinopeptide) from fibrinogen, while plasmin splits fibrin into a great many polypeptides. Both of the proteolytic enzymes are derived from an inactive precursor present in plasma. And finally, activation of the precursor to the active enzyme can be accomplished by either a tissue or a blood activator.

	Plasmin + fibrin	→	Fibrin is lysed into many polypeptides

Spontaneous Thrombolysis

Spontaneous thrombolysis is a biological phenomenon which has been observed and could be considered the antithesis of coagulation. It is both reproducible and predictable, and it indicates that there is a functioning homeostatic mechanism opposed to coagulation.[5,6]

Increased spontaneous thrombolysis has been reported[7] in obstetrical cases where there is a retained dead fetus or an embolism of amniotic fluid, and in cirrhosis of the liver. In these cases it may be due to a decrease in serum fibrinogen.[6] There are also reports of spontaneous thrombolysis following surgery, especially in thoracic procedures, in carcinoma of the prostate, in leukemia, after stress or exercise, in electric shock, in venous obstruction, and in injections of epinephrine, nicotinic acid, bacterial pyrogens and urokinase.[2,7] In these cases, no real decrease of fibrinogen has been reported.

Plasminogen (Proplasmin) and its Activators

Plasminogen is the inactive enzyme precursor of plasmin, forming plasmin by the splitting off of peptides.[7,8] It migrates with the serum globulins, has a molecular weight of 140,000, and is found both intravascularly and extravascularly and in certain body secretions. It is activated by a variety of substances: plasma activator in plasma, tissue activator in various tissues including blood vessels, bacterial activators such as streptokinase and staphylokinase; by other substances, among which are chloroform, acetone, alcohol and the pancreatic enzyme trypsin, and by activators present in some body fluids, notably urokinase, which is found in urine.[6,8] Of these activators, streptokinase has been the only one used extensively. It is now available in pure form, with only trace impurities, and is well tolerated in humans.

The presence of activators, such as urokinase, in certain body secretions, and similar activators found in milk and tears, have suggested that these represent excretion forms of the circulating activators. They may serve a useful purpose by preventing the formation of coagula which would obstruct the excretory ducts.[1]

Various tissues have been analyzed for the presence of tissue activator; the concentration has been found to be highest in the prostate, meninges and thyroid gland.[1] Prostatic carcinoma may result in spontaneous thrombolytic activity.

It seems probable that the activator substance(s) is derived from a proactivator, but there is little experimental support of this at present.

Plasmin[7,8] ("Fibrinolysin")

This is the active fibrinolytic enzyme and has a molecular weight of 108,000. It is a proteolytic enzyme (protease) of the trypsin class and resembles trypsin especially as to the type of linkage which it splits, and the pH optimum. It has rather nonspecific proteolytic ability in that it hydrolyzes, in addition to fibrin, fibrinogen, factors V and VIII, proaccelerin, AHF, some components of complement, ACTH, STH, glucagon, prothrombin, Christmas factor, and certain other blood proteins. It also hydrolyzes casein, thus providing one of the methods for determination of plasmin activity in vitro.

Plasmin Inhibitors[1,8]

It is evident that with the nonspecific proteolytic ability of plasmin, there must be some inhibitor to prevent it from causing widespread hydrolysis in the body. Postulated plasmin inhibitors include two antiplasmins, an inhibitor of the blood activator, as antistreptokinase, and E-aminocaproic acid. E-aminocaproic acid has been shown to inhibit as well as activate plasmin, and has provided a method of controlling thrombolytic activity where infused plasmin is used as the thrombolytic agent. The antiplasmins have not been adequately characterized; but it is known that one is found within the $alpha_1$ globulin plasma fraction and another in the $alpha_2$ fraction. It is probable that one of these is a fast-acting inhibitor, while the other inhibits slowly. Platelets have also been found to contain antiplasmin.

Specificity of Plasmin for Fibrin

Since plasmin is capable of hydrolyzing such a large number of substrates, what accounts for its specificity for fibrin? Two main theories have been proposed and experimental evidence provided for their substantiation. The first, proposed by Ambrus and co-workers,[7] proposes the existence of a circulating plasmin-antiplasmin complex, with effective competition for plasmin by fibrin. They injected isotope-labelled plasmin

Continued

into dogs and observed an initial increase of fibrinolytic activity, which rapidly disappeared. Yet the level of radioactive isotope remained high, and experimental clots exposed to this blood were slowly lysed. This led to the conclusion that an inactive plasmin-antiplasmin complex had been formed, and that the fibrin was able to compete effectively with this complex for the plasmin, which then resulted in lysis. According to this theory, thrombolytic therapy would consist of adding active plasmin to the patient's blood, thus providing a high level of circulating complex and continual but slow lysis of thrombi. The main concern would be to infuse the plasmin slowly enough so that the whole thrombolytic system would not be thrown into a generalized state of proteolysis, an eventuality which could be avoided by the infusion instead of the plasmin-antiplasmin complex.

The other theory, developed by Sherry and workers[4,7] proposes that when a thrombus is formed, it incorporates or adsorbs some of the circulating plasminogen, and that this occurs because the physical characteristics of plasminogen are similar to those of fibrinogen and fibrin. When circulating plasminogen is activated to plasma, it is immediately tied up by antiplasmin; but as the adsorbed plasminogen is slowly activated, the antiplasmin cannot attach to it, and slow lysis of the thrombus results. According to this concept, the level of activator in the circulation is more critical than the level of circulating plasmin. Sherry, therefore, has taken the approach of infusing the activator streptokinase in his experiments.

Use of Streptokinase

Sherry[4] has found that the plasminogen adsorbed on to the fibrin clot cannot be activated until all of the circulating plasminogen has been activated by high levels of circulating streptokinase. It is necessary to first give a priming dose, and then maintenance doses, to achieve adequate thrombolysis. The priming dose results in a state of hyperplasminemia, reflected by about a 30% decrease in fibrinogen levels, and occasionally by a hemorrhage. Sherry was able to avoid this latter complication by simultaneous infusion of hydrocortisone. After a short time all of the plasmin is inactivated by antiplasmin, and exhaustion of circulating plasminogen occurs. Then the proteolytic state decreases. About two hours after the beginning of therapy, active clot lysis begins and is dependent on the maintenance of continuously high levels of circulating streptokinase

There are, then, two phases in the effect on the fibrinolytic system produced by infused streptokinase. The first phase is proteolytic and is short, lasting only one to three hours. During this time, plasminogen undergoes rapid and complete activation and free plasmin is liberated into the circulation. If blood is drawn from a patient during this period it will clot and then lyse because of circulating active plasmin. During the second or thrombolytic phase the concentration of the activator reaches a high level and is maintained. This period will last as long as the infusion of activator continues. Plasminogen remains depleted, and all free plasmin has been inactivated by antiplasmin. Blood drawn from the patient during this phase will clot, but it will not then lyse spontaneously, because the plasmin is completely inhibited and there is no supply of plasminogen for adsorption to the newly formed clot. Without adsorbed plasminogen, there can be no activation to plasmin and no subsequent lysis of the clot. A clot which was previously formed will lyse, nevertheless, due to the high level of streptokinase which activates the previously adsorbed plasminogen.

Sherry[7] was unable to demonstrate effective clot lysis in the absence of a high level of circulating activator; he therefore challenges the validity of Ambrus' theory, despite the experimental support provided by the latter. Sherry[4] states further that it is unlikely that purified plasmin preparations can be developed for systemic thrombolytic therapy because:

1. Plasmin in the circulation has very little effect on a preformed thrombus, since it cannot activate the intrinsic plasminogen.
2. If clotting should occur in the presence of free plasmin, the resulting clot will be digested by this proteolytic enzyme. This would be of only limited prophylactic importance.
3. The presence of an activator which can diffuse into the thrombus and activate the plasminogen from within is necessary.

A unified concept regarding the in vivo specificity of plasmin for fibrin would be of help in resolving this conflict. Perhaps both are correct or, more likely, both contain elements which approximate the underlying reality.

Disadvantages of Thrombolytic Therapy

It has been suggested by several investigators[7] that there would be certain disadvantages to the use of thrombolytic agents, especially in treatment as advocated by Sherry, which is more intensive than that of Ambrus, is more costly, and requires careful laboratory control.

A major problem appears to be formation of antibodies to streptokinase from previous exposure to streptococcal organisms. Retreatment would be especially difficult because increased amounts of streptokinase would have to be used to neutralize the antibodies, and hypersensitivity reactions might occur.

No cases of embolism as a complication of lysis of thrombi have been reported.

A syndrome resembling the "crush syndrome" was reported in one patient. The re-establishment of circulation in a necrotic limb appeared to result in the absorption of toxins systemically, causing shock and death.

Clinical Experience with Thrombolytic Therapy

A major difficulty in evaluating the results of thrombolytic therapy in humans is the inability to be certain of the exact cause of a vascular occlusion. Similar clinical findings may result from embolic occlusion of a vessel, thrombosis, occlusion due to atherosclerosis, or perhaps even from vessel spasm.

One investigator[9] treated twenty-three patients with various types of arterial and venous thrombo-embolic diseases, using plasmin. Fourteen were felt to be inadequately treated because the dosage schedule was suboptimal. Of the nine who were adequately treated, eight were improved; in the one who was not improved, the vessel had been occluded by an old organized embolus. In most cases treatment was instituted within twenty-four hours after onset of symptoms.

Another group of seventy-one patients were treated with plasmin, with special attention paid to side effects.[13] Fifty were being treated for acute or subacute thrombophlebitis of a lower extremity. Twenty-one had

Continued

a temperature rise of over two degrees attributed to the therapy; four had shaking chills; three had asymptomatic hypotension; two had symptomatic hypotension; five had nausea and vomiting, and three had facial flushing. The authors concluded that, in spite of the high incidence of hyperpyrexia, plasmin was safe and beneficial in the treatment of thrombophlebitis.

In one series of 197 patients treated with thrombolytic therapy[2] only four instances of hemorrhage were noted. There was only a minimal increase in the prothrombin time, and, although there was a decrease in the fibrinogen concentration in 50%, the lowering was not to critical levels, even after 12 to 24 hours of therapy.

Of the 197 cases, 98 were cases of venous thrombosis, and 36, of arterial thrombo-embolism. The results are tabulated as follows:

TABLE 1

Results of Fibrinolytic Therapy in 98 Cases of Venous Thrombosis[2]

Duration	No.	Improvement Good	Improvement Fair	Improvement None	Average Treatment (days)
Acute, 5 days	48	40	7	1	2.8
Five to14 days	17	13	1	3	3.5
More than 14 days	23	13	4	6	4.1
Tumor or mechanical obstruction	10	0	0	0	3.0

Twelve of the patients were treated for pulmonary emboli:

Result	No.
Excellent	8
Good	1
Death	3

TABLE 2

Results of Various Types of Therapy in 36 Cases of Arterial Thromboembolism[2]

Time and Treatment	Total	Results Good	Results Improved	Results No Change
Prior to 1958	6	0	0	6
Since 1958				
Systemic only	17	5	4	3
Local only	7	4	0	3
Fibrinolysin plus femoral embolectomy	6	4	1	1

Thrombolytic agents have been advantageously used in conjunction with heparin.[11] It was found that there was no antagonism between the drugs and no increased incidence of hemorrhage over that which would have been expected with heparin therapy alone. The investigators felt that they had prevented the recurrent venous thrombosis experienced with earlier trials on thrombolytic therapy alone.

Experience with the use of thrombolytic agents in the treatment of acute myocardial infarction and cerebrovascular accidents is limited. A problem in the treatment of the acute myocardial infarction is that in 40 per cent there is no evidence of a fresh thrombus.[10,12] One investigator[12] treated forty-five patients with acute myocardial infarction with thrombolytic agents followed by treatment with anticoagulants. Thirty-nine survived and six died. It is still too early to draw any conclusions as to the clinical value of thrombolytic therapy in the stroke syndrome, but investigation in this regard is under way.

Case Report

A 43-year-old white man was transferred to Mount Sinai Hospital from another hospital on October 29, 1964. He had been admitted to the other hospital 10 days previously because of the sudden onset of severe shortness of breath without chest pain. This occurred while playing golf. Over a two-year period he had noticed a moderate increase in shortness of breath with exertion; however, he had otherwise felt well and had no symptoms. There had been no history of thrombophlebitis or heart disease. Before transfer to Mount Sinai Hospital he had been treated for right heart failure.

Physical examination on admission to Mount Sinai Hospital revealed a well developed and well nourished white male who was having moderate shortness of breath at rest. There was cyanosis present and the patient was orthopneic. The neck veins were markedly distended. Blood pressure was 120/80, pulse 86 and regular. The lungs were clear to percussion and auscultation. A friction rub was not heard. The heart was moderately enlarged to right and left and a presystolic gallop rhythm was present. The pulmonic second sound was louder than the aortic second sound. The liver was palpable to three fingerbreadths below the right costal margin. There were no masses in the abdomen and no ascites. There was minimal edema of the lower legs. Peripheral pulses were normal.

A chest X ray revealed decreased lung markings over the right lung compared to the left. Shortly after admission to the hospital a pulmonary angiogram was performed and revealed a complete block of the right pulmonary artery and poor filling of the left pulmonary artery.

At this time, because of the demonstrated block in the pulmonary circulation despite the history of 10 days since the onset of symptoms, it was felt that surgical exploration of the pulmonary arteries and an attempt at removal of any large thrombi was indicated. On October 30, 1964, a surgical pulmonary embolectomy was performed and multiple emboli were removed from both pulmonary arteries. However, during surgery the patient went into severe acute right heart failure and expired shortly after the surgery was completed.

Although thrombolytic therapy was not undertaken in this patient, it was considered, and if he had survived the immediate postoperative period, thrombolytic medical therapy would have been instituted. If an established effective form of thrombolytic therapy were available, surgical exploration in this patient might have been avoided.

WHAT WE DID (see page 1350)

The rosary was grasped through the esophagoscope and brought to the area of the cricopharyngeal muscle. However, at this point it caught, and cervical esophagostomy was required for the removal. The patient recovered without further complications from this incident.

Nonmetallic Implants

J. PHILLIP NELSON, M.D.*
JOHN C. IVINS, M.D.**
Rochester, Minnesota

NONMETALLIC IMPLANTS apparently were used for the repair of various bony defects at the time of earliest recorded history. Transplantation of bone from lower animals to injured humans is recorded in the medical writings of early Hindu, Egyptian, and Greek civilizations. Heterologous bone transplantation was apparently used quite extensively in the eighteenth and particularly in the early part of the nineteenth century. According to standard orthopedic reference books,[1] ivory seems to have been the first material other than heterologous bone used extensively with any degree of success. In 1884 Ogston performed a talonavicular arthrodesis for flat feet, apparently by using an ivory peg as a bone block, and in 1886 Bircher advocated the use of ivory for grafting because he thought it more "resistant" than heterologous bone. However, the predictably successful use of grafting had to await the development of strict antisepsis in graft preparation and in surgical technique.

Experience in both world wars demonstrated the need for materials which could be used as internal substitutes for body tissues, particularly in vascular and massive bony injuries. There was a marked increase in the use of autogenous grafting. Coincident with these developments, organic chemists were making rapid strides in the production of a great variety of stable polymers or plastics, a few of which have at least partially met the majority of physiologic and mechanical requirements for successful human implantation.

Definitions

In a fine review article published in 1960, Urist[2] clarified the meaning of a number of terms which have been used more or less interchangeably in much of the literature pertaining to this subject. A good deal of confusion can be eliminated if the following definitions are kept in mind.

Transplant or Graft

An autologous, autogenous, or isogenous sample of donor tissue that contains viable cells with the capacity for survival and growth in a new location without antigenic response.

Tissue Transfer

A term used to describe *fresh* homografts or heterografts because it is noncommittal with respect to cell viability and donor tissue survival.

Tissue Implant

Connotes nonviable, coagulated, frozen, or denatured tissue that does not contain cells having the capacity to proliferate or produce new tissue.

Continued

---

*Mayo Graduate School of Medicine (University of Minnesota), Resident in Orthopedic Surgery, Mayo Clinic and Mayo Foundation.

**Section of Orthopedic Surgery, Mayo Clinic and Mayo Foundation.

Tissue Derivative

This implies tissue from which one or more components, such as mineral, water, ground substance, protein, or lipid, have been removed.

Tissue Substitute

A synthetic material which is foreign to the body and which is introduced to function temporarily or permanently as a tissue, splint, or prosthesis.

In accord with these definitions, nonmetallic implants may be broadly defined as any materials other than metallic devices and autogenous bone, which are surgically placed within the body.

Criteria for Nonautogenous Materials[3]

To be *suitable*, a material: (1) must not produce inflammation or foreign body reaction; (2) must not elicit any stage of allergy or hypersensitivity reaction; (3) must resist mechanical strains secondary to the purpose for which the prosthesis was designed; (4) must be sterilizable; (5) must be noncarcinogenic; (6) must be amenable to fabrication in the desired form; (7) must not be physically modified by surrounding tissue; and (8) must be chemically inert. Criteria 7 and 8 have no application to bone implants (homogenous and heterologous) and bone derivatives, because the essential feature of their function appears to be their ability to act as a lattice for formation of new bone while they are simultaneously destroyed and absorbed by the host.

The major *obstacles* to the use of exogenous materials as implants include: (1) antigenicity and rejection; (2) foreign body reactions; (3) loss of substance or function; (4) infections; and (5) inadequate knowledge of final fate of implants and of possible metabolic, mechanical, and hyperplastic side effects.

Specific Materials

The discussion will be generally limited to those materials which have been proposed for some use in orthopedics, particularly as graft substitutes for autogenous bone.

Tissue Transfer

Fresh Homogenous Bone — The only application for the use of fresh bone from another individual of the same species is transfer between identical twins. Limitations on the use of this procedure are obvious.

Fresh Heterologous Bone — There is essentially no clinical or investigative interest now because of antigenicity and graft rejection.

Fresh Embryonic Bone — Only temporary graft survival can be expected and little practical use for such bone has been demonstrated.

Tissue Implant and Tissue Derivative

The materials classified under this heading are homogenous bone and heterologous bone which have been treated in one of a variety of ways in order to produce sterility as well as minimal or no antigenicity for grafting purposes. These categories will be considered together because of the difficulty in deciding whether bone tissue has only had its protein denatured or whether a portion of the osseous material has actually been extracted in the preparation.

Homogenous Bone — This is human bone used to stock bone banks. The following treatments have been utilized and found successful, at least experimentally, in the preparation of homogenous bone for use in grafting: refrigerated at 2 C; refrigerated in 0.9% saline at −5 C; frozen at −30 C; freeze-dried; coagulated with thimerosal (Merthiolate) solutions; sterilized and preserved by hydrogen peroxide; sterilized and preserved by beta-propiolactone solutions; and sterilized and preserved by boiling in glycerol and water.

Heterologous Bone — Long-standing interest in the use of heterologous bone as a substitute for human bone in grafting has been mentioned. Recently, clinical interest in this type of bone implant has been heightened by the introduction of a material called "processed heterologous bone."*

The experimental basis for the clinical use of this material in the United States was provided by Karges and co-workers.[4] Using macroscopic, histologic, tetracycline fluorescence, and microradiographic techniques, they showed that processed heterologous calf bone behaved biologically comparable to fresh autogenous bone in the process of host incorporation and remodeling of bone implants. There were two exceptions to this generalization. The first was that fresh autogenous bone took up mineral rapidly during the first two weeks, whereas the heterologous bone did not; however, after one month there was no appreciable difference in mineralization between the two types. The second exception was that there was more remodeling of the cortical heterograft than of the cortical autograft at six months. They concluded that:

---

*Boplant, E. R. Squibb & Sons.

"Evidence indicates that antigenicity of the calf-bone heterograft has been lowered effectively without adversely altering its structural characteristics. This, in conjunction with effective eradication of cellular debris from the large trabecular and macrocanalicular spaces and negligible fat content in the calf-bone heterograft, has enhanced its effectiveness as a bone transplant to compare favorably with the autograft."

Processed Heterologous Bone

Primarily on the basis of this experimental evidence, Anderson and co-workers[5] proceeded to use processed heterologous bone clinically. They did 452 grafting procedures and had a follow-up of more than six months on 351 patients. They reported the infection rate as 1.3% and successful graft rate as 85%. In spite of the difficulties inherent in determining nonunion and the bias of clinical authors evaluating their own results, it would seem that these results compare favorably with those in other series in which homografts and autografts were used.

Advantages

According to the manufacturer, processed heterologous bone offers a number of advantages:

1. The problems of antigenicity, failure of graft assimilation, and sterility have been solved.
2. Lyophilization* and packaging in partial vacuum have rendered the material easily transportable and available as well as enabling storage at room temperature.
3. This material provides wide and open marrow spaces for invasion by blood vessels of the host.
4. The mechanical stability of this type of implant equals that of autogenous bone.
5. The problems of an insufficient autogenous bone supply for some procedures and of creation of a painful donor site are eliminated.
6. Operative infection rate is as low as that found with use of autogenous bone and lower than that found with use of homogenous bone.
7. The problems of bone-bank-processing, bacteriologic control, provision of the proper type of bone, and medicolegal considerations are eliminated.
8. Average costs of equal amounts of homogenous bone and processed heterologous bone in some institutions are $150 and $30, respectively.

From these glowing reports, one could surmise that an almost ideal substance for bone grafting has been found. However, such a conclusion is premature until more extensive clinical experience with long-term follow-up is gained.

It should be mentioned that other methods of preparation of heterologous bone have been used with at least some degree of success. These include complete freezing,[6] autoclaving,[7] and defatting with sterilization in alcohol solutions.[8] These methods all produce protein denaturation and hence decreased antigenicity; but they have not been brought to the apparent level of sophistication and mass production found in the Squibb process.

Bone Derivatives

Bone derivatives made by treatment with various other chemicals to remove specific components of bone have been used as implants in experimental situations. The purpose of these methods is to produce a substance which has decreased antigenicity or which is more rapidly absorbed by the host, compared to autogenous, homogenous, or heterologous bone. *Decalcified bone* is made

Continued

---

*See Test Your Word Score Page 1333.

by extraction with either acid or ethylenediaminetetra-acetate (Versene).[9] *Deproteinized bone* is the result of treatment with ethylenediamine[10] or hydrogen peroxide,[11] which removes most of both collagenous and noncollagenous (protein?) material of bone. This derivative apparently is not well vascularized and has little mechanical strength.[12] *Collapatite*[13] and *os purum*[14] are derived from bone by extraction with urea-8.8% saline or potassium hydroxide, respectively. Collapatite ("collagen and hydroxyapatite") is an inert, hard substance with a microcanalicular system which is replaced more slowly than that of bone and apparently is the product of extraction of intracellular proteins and mucoproteins. Both of these materials have been recommended as substitutes for internal fixation but not for filling bone defects.

Tissue Substitutes

Orthopedists with a taste for science fiction should be interested in McFarland's[15] speculations written 15 years ago. Writing as of the year 2000 A.D., he commented on the ever increasing number of injuries resulting from the general use of helicopters:

> "Fortunately, this increase in the frequency of bone fractures has been unimportant because intramedullary fixation with thermoplastic, homoplastic agents injected directly into the fracture site, cancellous in their form, setting to the resilience and strength of steel, stimulating callus formation, and being resorbed in that process, has permitted weight-bearing in nearly every fracture."

Quigley[16] suggested that the present state of knowledge regarding the use of organic polymers or plastics is similar to that which prevailed regarding the use of metals in the early part of the twentieth century when the fundamental principles of mechanics and electrolysis were not appreciated. Although there has been a remarkable increase in the study of the surgical applications of these materials, with few exceptions none seems to offer advantages over more traditional treatments. On the contrary, it seems that there is a general state of confusion about indications for orthopedic use of implant plastics, and many human implantation experiments have ended disastrously.

The following substances have received substantial clinical trial.

Polyurethane (Ostamer)

The initial reaction of a monomer of urethane with a catalyst forms a liquid material which is then poured into a bony defect; it hardens in 15 to 20 minutes into a rigid, spongelike material due to the liberation of CO_2 during polymerization. When the use of polyurethane was first proposed by Salvatore and Mandarino[17,18] in 1959, it seemed that McFarland's speculations might be coming true, because the material was advertised as having enough strength and cohesiveness to permit almost immediate weight bearing, as being nontoxic, as promoting osteogenesis, and as being easy to handle. Subsequent studies by other investigators[19,20] have failed to substantiate these claims.

Methyl Methacrylate or Acrylic (Lucite)

This material has become familiar to orthopedists because of its initial use in the Judet hip prosthesis.[21] Primarily because of its tendency to fracture and erode, it has been discarded for prosthetic uses and is now used primarily to fill skull defects[22] and for dentures.[23] It has been tried, unsuccessfully, as a hip mold.

Tetrafluoroethylene (Teflon)

The successful use of Teflon fibers woven or knitted into fabrics as protheses for the aorta and large vessels is well known. It is the most chemically inert substance for implantation now known. Charnley[24] has devised a hip arthroplasty which utilizes a precast Teflon socket with deep serrations on its outer surface and a ⅞-inch prosthetic head. Walldius[25] has implanted a metal knee-prosthesis with a Teflon layer over its articular portions in 64 arthritic knees; results were classified as good in 64% of cases. Teflon was used in prosthesis construction because of its low coefficient of friction and its resistance to mechanical abuse. It has been used unsuccessfully as a tendon and tendon-pulley substitute in dogs.[26]

Silicones (Silastic)

The chemical structure of these materials consists of long chains of silicon and oxygen atoms in alternation and resembles that of natural rubber, plastics, and oils which are made up of long chains of carbon atoms. They are produced as fluids of varying viscosities or as rubbers which have varying strengths and elasticity. Room-temperature-vulcanizing (RTV) silicone rubbers utilize stannous octoate as a catalyst. The advantage of this material is that it can be injected or poured, with its catalyst, into a soft-tissue defect and it will cure in situ. The silicones are heat stable, are unaffected by time, do not adhere, and do not induce tissue reactions.

Silicones have been used primarily in plastic surgery in such diverse ways as breast and facial tissue augmentation and prevention of readhesion after separating bony temporomandibular ankylosis or prevention of premature fusion in craniosynostosis. RTV silicone polymer has been poured around aneurysms of the circle of Willis; 40,000 Holter valves have been implanted as permanent drains for hydrocephalus. It is used routinely in operations for detached retinas and as a replacement for vitreous humor. The most widely used prosthetic heart valve (Starr-Edwards) utilizes a silicone-rubber ball. In orthopedics, this group of materials has been used as a sheathing to prevent adhesions after tendon graft, as a matrix for the creation of new autogenous tendon sheaths, as direct artificial implants for tendons, and in the prevention of readhesion following release of radioulnar synostosis. It seems safe to predict that many more uses will be found for these compounds because of their inertness and physical versatility.

Other Plastics and Polymers

These have received substantial experimental evaluation but in general seem to have little potential for orthopedic uses. *Polyvinyl alcohols* (Ivalon) have been tested as orbital[27] and breast[28] implants; they seem to provoke a dense fibroblastic response. *Polyethers* (Etheron) also have been implanted as tissue augmenters.[28] *Polyethylenes* (Marlex) have been fabricated into porous, strong materials which have been implanted for tracheal reconstruction.[29] *Coal-tar derivatives* (nylon) are well known as suture materials; they were used briefly and with very undesirable results in hip[30] and knee[31] prostheses in the early 1950s and, more recently, have been fabricated into a mesh incorporating a cellulosic material (Millipore-Microweb)[32] for use (with encouraging results) as a filter allowing tissue fluid diffusion but not fibroblastic infiltration into tendon anastomoses. *Cellulose derivatives* (cellophane) have also been used as a sheathing material after synovectomies and section of synostoses. *Polyesters* (Dacron), another familiar type of polymer, have been used as fabric for vascular prostheses. Starch sponge has been tested as bone filler.[33]

Plaster of Paris

Peltier[34] claimed excellent success with use of sterile gypsum (the hemihydrate of $CaSO_4$) as an implant for filling large bony defects. The plaster of Paris is absorbed simultaneously with new bone formation, does not seem to interfere with or promote osteogenesis, and seems to act as a filler to retard fibroblastic infiltration while osteogenesis proceeds. Peltier presented 20 healed cases in which this implant material was used, even in the presence of infection.

Ceramic-Epoxys

A mixture of alumina, silica, calcium carbonate, and magnesium carbonate heated at 2,700 F. produces a true interconnecting-porosity ceramic. When this material is impregnated with an epoxy resin, a lightweight, inert material, as strong as bone and with bone's elasticity, is produced. This material has been suggested as a bone substitute.[35]

Modified Protein (Bioplast)

This is an absorbable material made by compressing fibrin under high pressure. The material is molded and used as a cup for hip arthroplasties in the treatment of tuberculo-

Continued

sis. According to its proponents,[36] it should be used in joints that show minimal destruction after two to three months of antituberculosis chemotherapy. The material is apparently neutral to tuberculosis, does not stimulate tissue reaction and, since it is subject to proteolytic breakdown in three weeks to eight months, serves as a temporary protective device to allow cartilage regeneration. Residual hip stiffness has apparently been a problem.

Gelatin — This animal protein derivative has also been tested as a bone filler.[37,38]

Summary and Conclusions

One can easily surmise from this brief report that the subject of nonmetallic implants is an expanding and promising field. Medical research has produced several materials that have wide clinical application. Results of preliminary testing with processed heterologous bone (Boplant) are encouraging, and the material seems to compare favorably with autogenous bone for grafting. The plastics, particularly Teflon and the silicones, have found uses in a variety of surgical problems but, with the possible exception of tendon surgery, offer no advantage over metallic implants or traditional procedures in orthopedics. Despite the failure of polyurethane (Ostamer) it seems that the realization of McFarland's predictions may come in the not so distant future.

The Tobacco Tyrant

There are two schools within the medical profession on the effects of the use of tobacco on the human economy. Were it not for the fact that members of our profession are among the chief devotees of the weed, the chances are, I believe, that there would be but one school of thought on the question, and that this thought would be told and expounded in a broader and more energetic manner than it is today. As proof of the evil effects of tobacco on the human system, I herewith present abstracts from literature on the subject, recorded by reputable and representative men of the medical profession:

Gould's Medical Dictionary puts it this way: "Tobacco is a plant, Nicotiana Tabaccum, the dried leaves of which contain a liquid alkaloid, Nicotine. Nicotine is one of the most active poisons known. Tobacco smoke contains a series of bases, among which are pyridine, picoline, lutidin, and others. Tobacco is used as a sedative in nearly all parts of the world, being smoked, chewed, or used as snuff. Its physiological action is that of a nauseant, antispasmodic and depressant. It is also a local irritant."

**Editors Note:* *This is a somewhat belated publication. In 1928 Dr. E. O. Giere, M.D. prepared and presented a manuscript at one of the Twin City hospitals on the evil effects of tobacco.*

Through the courtesy of his sons, Richard and Joe Giere, the timeworn and faded manuscript was made available to the editor. The contents seem more pertinent today than they were in 1928 when the manuscript was written.

Abstracts, Briefs and Commentaries

GASTRIC HYPOTHERMIA FOR DUODENAL ULCER

The medical literature indicates that gastric hypothermia for duodenal ulcer has not proven to be wholly successful, though approximately 50 per cent have continued to remain asymptomatic after one year. Repeated freezings have been used to control recurrent symptoms. The authors who indicate that the gastric mucosa temperature is usually not decreased below 0° C. may prefer to use the term gastric hypothermia in preference to gastric freezing.

The authors analyzed three groups of patients on the basis of the inflow-outflow temperature ranges. They observed the depression of the free hydrochloric acid, the X pepsin excretion and the clinical response in each of these three temperature categories.

In the cold group with the outflow of $-14.1°$ C. the results were best, showing excellent in 100 per cent after nine months. In the intermediate group with the outflow temperature of $-12.8°$ C. there were 33% presenting excellent results, and in the warm group with a temperature of $-11.1°$C. there were no excellent results at the end of twelve months.

These authors were able to conclude that gastric hypothermia is not a cure-all; nor is it worthless in the treatment of duodenal ulcer. They considered that the majority of patients can expect some benefit providing the temperature of the gastric mucosa is sufficiently depressed. They also indicated that there is a direct relationship between the degree of temperature depression and the decrease in the basal gastric acid and an increase in the X pepsin excretion and over-all beneficial clinical effectiveness. The colder temperatures provided the best results.

Though there are a few enthusiastic proponents of gastric hypothermia for duodenal ulcer, the preponderance of physicians are willing to await more definite evidence favorable to gastric hypothermia before adopting it as the accepted method of treatment for duodenal ulcer.

OPERATIVE TREATMENT OF ADENOCARCINOMA OF THE ENDOMETRIUM IN OBESE WOMEN

Among 486 women who received primary treatment for adenocarcinoma of the endometrium at University of Minnesota Hospitals between 1939 and 1963, 98 (20.2%) weighed 200 pounds or more and were classified as obese. Five weighed more than 300 pounds, and one over 400. There was no significant difference between the obese and nonobese groups in age or parity. About 30% were nulliparous. Of the obese group 65% were evaluated for abnormal carbohydrate metabolism; of these, 52% exhibited some evidence of clinical or latent diabetes.

Although the mode of therapy during this time period was changed periodically to conform to a long-term planned program of treatment to determine the effect of radiation therapy in the treatment of this disease, total hysterectomy with bilateral removal of the adnexa was performed as frequently as possible as complete or partial treatment in both the obese and the nonobese groups. When surgical removal of the uterus and adnexa constituted partial treatment, preoperative intracavitary radium with or without external radiation therapy was also given.

Of the 98 obese patients, 88 (90%) underwent operative treatment with only three (3.4%) operative deaths. Abdominal total hysterectomy with removal of the adnexa was performed in 77 patients. Five of the remainder underwent vaginal hysterectomy, one radical hysterectomy, and five were deemed inoperable at exploratory laparotomy.

When the results of therapy among these obese patients were compared with the results among the nonobese who received the same therapy, the five, ten, 15, and 20-year survival rates among the obese women were equal to or better than among the nonobese. The total five-year survival rate among obese women was 65%. Of those who did not survive five years 17% died of recurrent disease, 9% had untreatable disease when first seen or refused treatment, and 6.5% died of causes unrelated to endometrial cancer.

This summary of operative treatment of adenocarcinoma of the endometrium demonstrates that obesity alone should not be a deterrent to operative attack upon the disease. The results reported were achieved with little attempt at preoperative weight reduction and no compromise in the mode of therapy. The 90% surgical and the 3.4% surgical mortality rates compare with 70% and 4% surgical and surgical mortality rates considered usual and acceptable when all patients with this disease are considered, regardless of weight. The authors attribute the results in this series to detailed preoperative evaluation of the general health status of the obese individual, careful surgical technique, and meticulous postoperative management.

PREVENTION OF PYELONEPHRITIS BY WATER DIURESIS

The medulla of the kidney has been shown to be more susceptible to infection than the cortex. The authors contend that at least a part of this vulnerability is due to the hypertonicity of the renal medulla.

They were able to induce a chronic water diuresis in female Sprague-Dawley rats by simply adding 5% glucose to their drinking water. Injections of laboratory strains of Candida albicans and Staphylococcus aureus were given intravenously to diuresing and normal control animals. These strains are known to cause infections of the renal medulla of normal rats. The animals were sacrificed at varying times up to eight days after inoculation. Urine cultures, cultures of homogenized kidney tissue, and histological sections were studied. In addition, spleens, livers, and blood were cultured and studied microscopically.

Water intake increased several fold without affecting blood sugar or causing glycosuria. Urine from experimental animals had low osmolarity and higher pH (mean value 7.88 as compared to 7.14 for control animals).

Sixteen of seventeen controls receiving Candida injections had pyelonephritis when sacrificed eight days later. Only three of seventeen experimentals had positive cultures, and none of these had the gross abscesses commonly seen in the controls.

Twenty of twenty-one controls receiving Staphylococcus developed pyelonephritis. When diuresis was begun one day before injection, only three of twelve animals were infected; when diuresis was begun one day after injection, only four of twelve animals were infected.

When Staphylococcus-treated animals were started on diuresis as much as three days after injection, six of thirteen animals were infected when sacrificed five days later. Since renal infections and abscess formation occur between 24 and 48 hours after injection of this strain, some of these rats must have been cured of their infection. Renal infection was not prevented or cured by three days of diuresis when it was started five days after injection.

Staphylococcus never appeared in the urine of animals undergoing diuresis, indicating that the organisms were not simply "washed out." In vitro studies demonstrated no bactericidal substance in renal medulla extracts from experimental animals.

These studies demonstrate that Candida and Staphylococcus renal parenchymal infections can be prevented, and suggest that Staphyloccal renal infections can be cured by decreasing the hypertonic environment of the renal medulla through sustained water diuresis.

Concentrated urine and saline solutions are known to inhibit phagocytosis. More dilute urine does not.

Hypertonic solutions have also been shown to inhibit the action of complement. Complement, lysozyme, and antibodies are known to injure the cell walls of urinary pathogens, causing the formation of protoplasts, which are lysed in isotonic or hypotonic environments, but preserved in hypertonic solutions.

Water diuresis induces an increased renal blood flow, which may play a part in the delivery to the kidney of more phagocytes and increased amounts of serum factors involved in body defenses.

The authors feel that this study "provides an experimental rationale for

Continued

the time-honored practice of 'forcing fluids' in patients with urinary infection."

TOXICITY OF SODIUM BISULFITE IN PERITONEAL DIALYSIS SOLUTIONS

Toxic symptoms typical of central nervous system stimulation were observed in using certain peritoneal dialysis fluids according to scientists at the University of Michigan. Sodium bisulfite was the causative agent.

The dialysis solution was prepared by a commonly used formula and contained 7% dextrose, 0.62% sodium chloride, 0.39% sodium lactate, 0.026% calcium chloride, 0.015% magnesium chloride, and 0.05% sodium bisulfite. Control data revealed no reason for the toxicity. During investigation of the formula, the authors found that the amount of sodium bisulfite was unusually high, based on the volume of fluid which may be used (10 to 12 liters in 24 hours). Consequently, if appreciable absorption occurred from the dialysis fluid, this quantity of bisulfite (500 mg. per liter) could be dangerous.

Sodium bisulfate is used to prevent discoloration of dextrose (and other items) in various solutions and may be used in concentrations up to 0.31%. However, these solutions are not administered in amounts as large as those used for peritoneal dialysis.

To evaluate the absorption, tissue distribution, and urinary excretion, S^{35}-labeled sodium bisulfite was used in the dialysis fluid and it was injected intraperitoneally into rabbits. Blood-level measurements showed that the bisulfite was absorbed rapidly from the dialysis fluid with the rate decreasing as the blood level increased. Some elimination of bisulfite was effected by urinary excretion and also by oxidation to sulfate. However, these mechanisms are limited and proceed too slowly or almost cease entirely, while absorption continues at a faster rate than elimination. Therefore, an accumulation of bisulfite in the tissues occurs, and if a sufficient concentration is reached, the central nervous system is affected and cardiovascular collapse results.

The authors conclude that, although the testing thus far is limited, the results do show that bisulfite should be greatly limited or excluded entirely from the final product.

They suggest that some bisulfite is oxidized to sulfate during manufacture. If an amount could be added which would be sufficient to protect the dextrose, but which would be almost completely utilized during processing, the limit on bisulfite content could be placed on the final product. Then it would not be necessary to eliminate bisulfite entirely, since an amount would not be present which might prove hazardous to the patient.

CLINICAL ASPECTS OF BENIGN PROTEINURIA

Proteinurias identified as benign may have several causes. The author calls attention to an orthostatic form that occurs chiefly in young persons, in some while they are standing or walking, in others only after they assume a lordotic posture. Benign proteinuria also occurs after great physical exertion either in the form of exercises (sport activities) or of hard physical labor. Excitement or exposure to cold likewise may bring on reversible, benign proteinuria. Discussing the mechanism involved in these forms of proteinuria, the author suggests a common etiological process. While the proteinuria that characterizes congestive heart failure is probably the result of increased pressure in renal veins, this cause plays no part in benign proteinuria. The importance of slight structural changes in the glomeruli is questioned. The author describes observations on four adolescents with benign persistent proteinuria. The condition was not related to posture, and the findings on clinical examination and clearance tests were normal. Percutaneous renal biopsies likewise revealed no abnormalities. The author stresses, however, that the diagnosis of benign proteinuria should be made only after the exclusion of pathological conditions, and these patients should be kept under observation for long periods.

REMINISCING IN THE AGED

Reminiscing, the habit of relating past experiences, was studied in 25 noninstitutionalized Spanish-American War veterans between the ages of 78 and 90. The tendency to reminisce was compared in each subject with (a) the degree of intellectual deterioration, (b) the presence or absence of depression, and (c) two-year survival after the interview. Findings suggest a positive correlation between the tendency to reminisce and freedom from depression and survival since the interview. It was not related to intellectual deterioration. There is a discussion of factors which favor reminiscing behavior as well as some of the psychological meanings of reminiscence and some ways in which it contributes to successful adaptation to senescence.

PHYSICAL EXERCISE IN BREATHLESS SUBJECTS WITH PULMONARY EMPHYSEMA

Breathlessness on exertion limits the physical activity of patients with severe pulmonary emphysema to such an extent as to result in physical unfitness and muscle atrophy. Oxygen inhalation during a graded exercise program overcomes this handicap in some cases. In many others, restoration of diaphragmatic function during walking is required even with the use of oxygen. The technique of breathing training required for effective use of oxygen-supported exercise is described. Elimination of a disordered

Continued

breathing pattern in patients with obstructive pulmonary emphysema is shown to result in a more effective alveolar ventilation, and a consequent increase in the capacity for exertion. If tobacco smoke does not enter the lungs, the question is propounded: is there justification for an adamant position in respect to rejection of cigarette smoking.

ULCERATIVE COLITIS AND REGIONAL ENTERITIS

A review of surgical specimens from 57 cases of ulcerative colitis showed 35% to have involvement of the ileum. Eighteen cases of regional enteritis were also reviewed and 22% of these had involvement of the colon. These two disease entities were found to be distinct and distinguishable from each other regardless of the segment of intestine involved; the lesions of ulcerative colitis were primarily of the mucosa while those of regional enteritis were primarily of the submucosa and subserosa. The morphological differences between these two diseases and the rarity of their occurring together in the same patient are strong evidence against these diseases sharing a common etiology. Diagnosis and treatment should be based on the principle that these two diseases are distinct and distinguishable, regardless of the segment of intestine involved.

The Horus Eye

In ancient Egypt the udjat-eye (Horus Eye) was a sacred symbol of healing and medicine — corresponding to the familiar caduceus of today's medical profession.

The Horus Eye derives from the myth of Osiris, the sun god, who was killed by his brother, Set, and avenged by his son Horus. While engaged in slaughtering Set in reprisal for Osiris' murder, Horus suffered irreparable damage to one eye; however, the god Thoth miraculously restored it by spitting upon it. Not only did the eye completely recover; it was henceforth exalted to divine status as possessing magical curative properties.

Conventionally the Horus Eye consists of an eye within an equilateral triangle based like a pyramid — with Osirian sun rays emanating from all sides.

So vitally imbued with the Osiris myth was the ancient culture of the Nile that the Horus Eye became a popular pattern for therapeutic amulets, some of which, handsomely wrought of faience and jewels, can be seen in modern museum exhibits of early Egyptian art.

Even today the Horus Eye appears in modified character on some medical prescription forms and in some drug stores. Furthermore, its original significance either forgotten or ignored, the Eye makes a nontherapeutic appearance on our currency. Anyone intrigued enough to look can find it on the back of any one-dollar bill, where it apexes the pyramid on the reverse side of the Great Seal of the U.S.A.

Counting time is not so important as making time count. — James J. Walker

THE FADING FAMILY PHYSICIAN — by Judge M. Lyle, M.D., Henry L. Geddie Co., $3.00 postpaid. Orders accepted at Book Dept., 510 S. Ballinger St. Fort Worth, Texas.

One man's experience as a general practitioner over a span of forty years has been incorporated into The Fading Family Physician, by Judge M. Lyle, M.D., just published by Henry L. Geddie Co., Fort Worth, Texas. Dr. Lyle recounts his experiences as a Mississippi farm boy and his early years in medical school, tells of the many things that can happen to a doctor engaged in general practice, and draws the conclusion that the modern type of family physician is giving way to the specialist.

"Many feel that the General Practitioner or the family doctor will fade out entirely except in the rural areas where one cannot easily reach the city or a hospital," Dr. Lyle writes. "Too, a lot of medical literature has been advocating that the medical internist become the family doctor. Some of the specialists think that the family doctor should be done completely away with in the cities and the diagnostician should fill his shoes."

"I feel that we must make the patient the central unit and co-ordinate everything for his good and well-being," Dr. Lyle writes.

HOW DIABETICS CAN EAT WISELY — Dorothy Tompkins Revell. T. S Denison. Minneapolis. 1964, 172 pages.

Mrs. Revell is the dietitian for the Dakota Clinic in Fargo. She has written in this little book a handy kitchen aid for the diabetic or his cook. The new diabetic, saddened by the gastronomic insult of a diet list on a sheet or two, can turn gladly to such a book as this for relief from the monotony of a rigidly enforced diet. Mrs. Revell clearly indicates the wide choices that are available within the limits of a diabetic diet.

She recommends polyunsaturated fat, and many of her recipes for diabetic foods include such oil. As Kinsell puts it in his foreword: "It is still not possible for anyone to promise the diabetic who follows such a program that he will have major protection against the development of blood vessel disease, but it seems increasingly probable that this is so." The recipes, to this reviewer who knows his way about a kitchen, seem occasionally somewhat incompatibly compounded, as, for instance, green grapes halved served with canned salmon; or fresh apple and chicken salad. An occasional sentence loses its meaning in the shuffle of words: "Sometimes it is necessary to substitute and/or clear liquid foods for solid food."

CURRENT PRACTICE IN ORTHOPAEDIC SURGERY — Volume 2, 1964, Adams, $13.50.

The second volume of this series should appeal to the general surgeon as well as the orthopaedic surgeon. Five of the nine chapters deal with fractures, including a very interesting discussion on the management of acute vascular injuries of the extremities authored by Paul Gryska, R. Clement Darling, and Robert R. Linton.

It seems to this reviewer that the greatest advantage to this type of yearly publication over a formal text rewritten every four to five years is that the topics covered in each new issue can relate to recent advances in orthopaedics. The fourth chapter on vascular injury is a step in the right direction. The volume in general should be favorably received.

MODERN TREATMENT — A bimonthly publication. $16.00 per year. Harper & Row, New York.

MODERN TREATMENT consists of a series of symposia dealing in an up-to-date fashion with problems that are of interest to every practicing physician. Among the forthcoming symposia are the topics of epilepsy, headache, menstrual disorders, arthritis, intestinal malabsorption and acid peptic disease. The subscriber to MODERN TREATMENT can look forward with pleasurable anticipation to these well documented paperback symposia.

Anturane®
brand of sulfinpyrazone

Dosage
Anturane, brand of sulfinpyrazone, is available as white, scored tablets of 100 mg. Initially, give half a tablet 4 times daily with meals or milk, increasing in one week to one tablet q.i.d. Increase to two tablets q.i.d. if necessary, and reduce if possible to as low as half a tablet q.i.d. after control. Continue through acute attacks, which can be concomitantly treated with phenylbutazone.

Patients on other uricosurics may be transferred to this drug at full dosage.

Contraindications
Active peptic ulcer. Salicylates and citrates antagonize the drug's action and are contraindicated for concomitant use.

Warning
Use with caution in pregnant women.

Precautions
Keep patients under close supervision and make periodic blood counts. Use cautiously in patients sensitive to pyrazoles, in patients with histories of peptic ulcer, and in conjunction with sulfa drugs, the sulfonylurea hypoglycemic agents, and insulin, the actions of which may be potentiated.

In mobilizing urate deposits, the drug may precipitate acute attacks of gout, urolithiasis, and renal colic, especially in the initial stages of therapy. Ensure adequate fluid intake and alkalinize the urine. With renal impairment, test renal function periodically.

Adverse Reactions
The most frequent are upper gastrointestinal disturbances. The drug may activate peptic ulcer. Rash occurs infrequently. Although not reported to date, blood dyscrasias are a possibility.

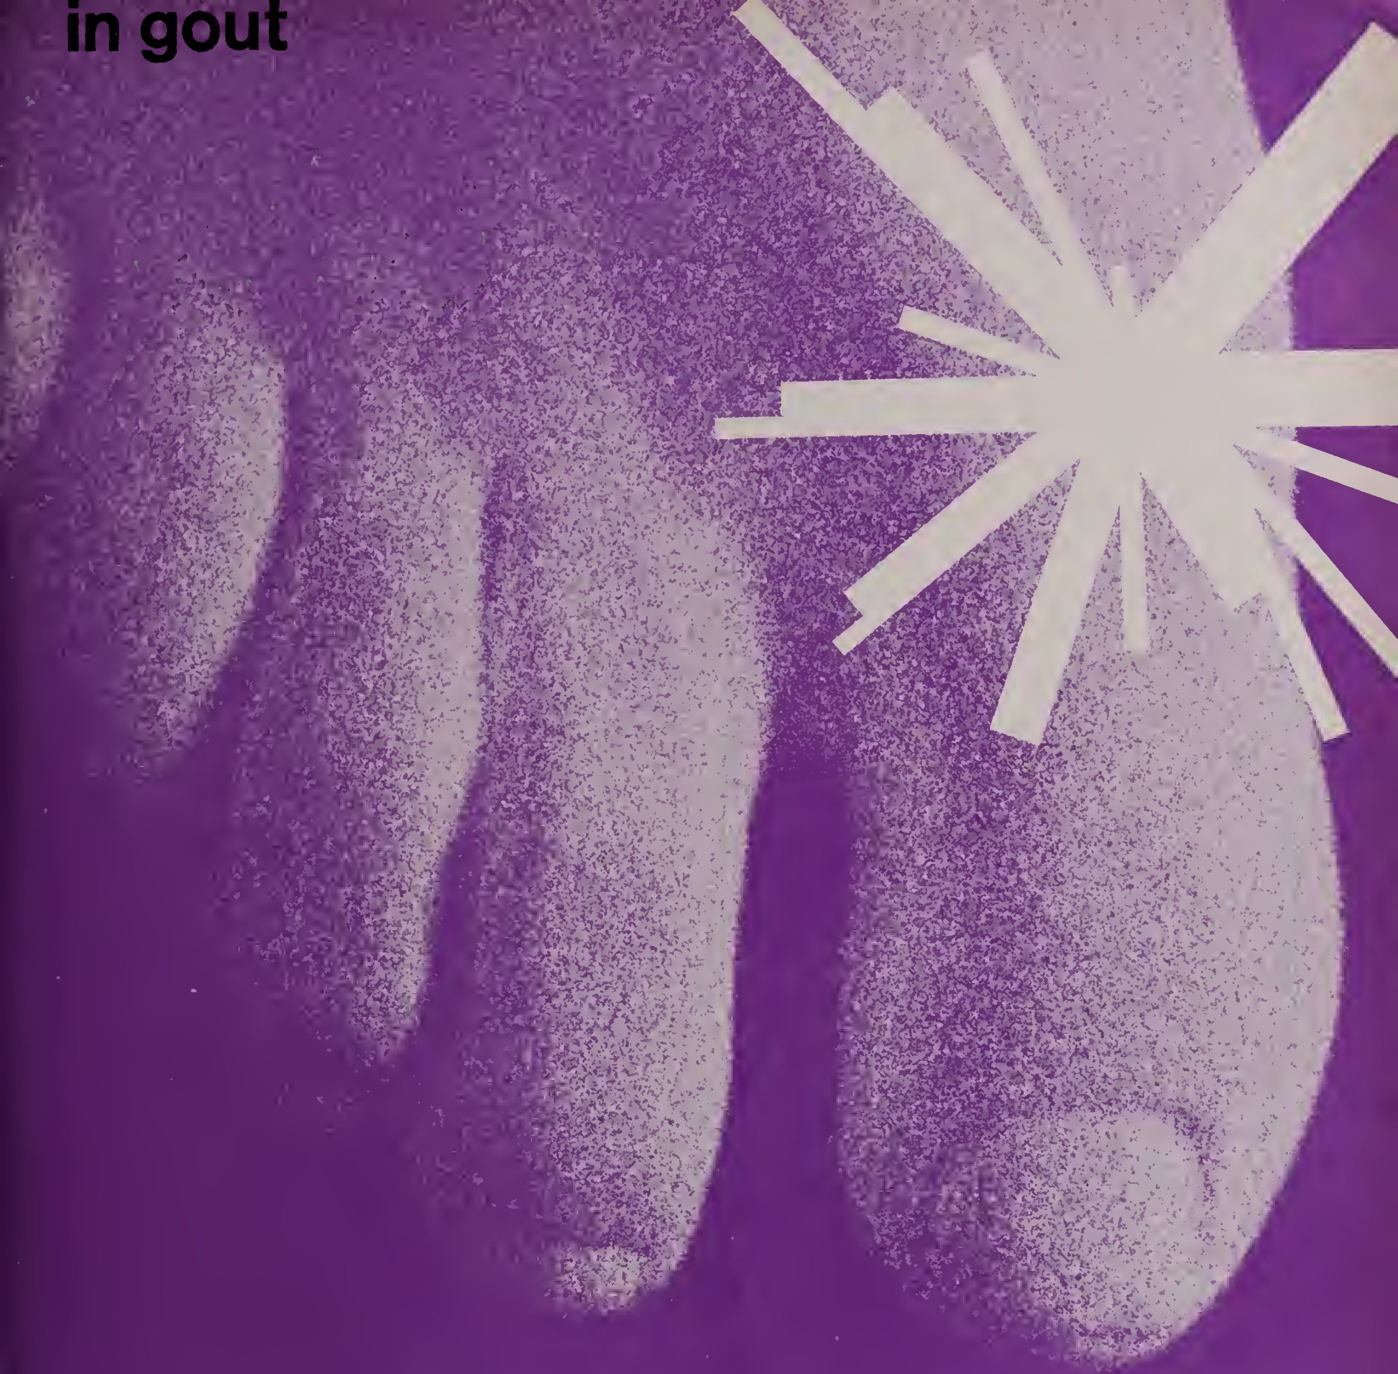
in gout



Anturane®
brand of sulfinpyrazone

"the most effective and best tolerated of the currently available uricosuric agents for the control of gout."*

Anturane, brand of sulfinpyrazone, was developed in the Geigy laboratories. Its pharmacologic activity is limited almost exclusively to increasing the urinary excretion of uric acid. For this reason, it is a drug of choice in chronic tophaceous gout and acute intermittent gout. It is not intended for relief of acute attacks of gout.

In most patients, the drug rapidly reduces serum uric acid levels to normal. This not only prevents new tophi but also mobilizes and promotes the excretion of urates already in the tissues. The reduction of tophi and periarticular crystals results in more mobile, less painful joints

Anturane, brand of sulfinpyrazone, materially reduces the number and severity of acute attacks of gout. It may also be used to counteract hyperuricemia induced by certain diuretics.

Because of its potency, the drug is often effective in patients refractory to other uricosuric agents. Patients can usually be maintained indefinitely on it without cumulative effects or development of tolerance.

For Pains in the Limbs

"For Pains in All the Limbs" the Scribe (of the Egyptian Papyrus) made a good start by instructing the Patient to mix up Castor Oil with Honey; but in the next few lines he spoilt everything by telling him to smear this all over the outside of his body instead of swallowing it and allowing it to do its work internally. Of course having got off the track at the start he found it impossible to right himself and accordingly went from bad to worse, his next effort being a poultice of Locusts which have been ground up in a mortar with Butter and Spices. For 'Pains in the Bones in Every Limb according to the Truth,' he recommended a poultice of Black Knife-stone with Fat, Honey, and Saltpetre as adjuvants. But according to the truth as we know it the use of Black Knife-stone, with or without Fat, Honey, and Saltpetre, in this connection is entirely fallacious, and not to be commended. The same can be said of the special poultice for the Thigh:

Bean-meal
Meal-of-the-pesen-bread
Sea-salt
Human Urine
Cook into one and apply as a Poultice.

And also for the Front-of-the-Shins, which was, however, let down more lightly:

The Inner-of-the-Shadfish; what is found in its Head
Soak in Honey and apply as a Poultice.

It Will Heal the Patient Forthwith.*

Regulatory Factors of Coronary Blood Flow

W. F. GEBER, Ph.D.*
Vermillion, South Dakota

THE STUDY OF the coronary circulation is actually a series of controversies, many of which have important clinical implications. Certainly the coronary vasculature functions under conditions much different from other systemic circuits. Many of the factors which regulate or modify the coronary hemodynamics are similar to those operative in all vascular beds. Others are apparently limited to the coronary system. Thus, in spite of the interest and the many investigations that have been carried out on the coronary vascular system, it still remains an enigma in many aspects.

Anatomic Position

Certainly not the least among the reasons for the situation mentioned above is the fact that the heart is approached only with some obvious disruption of its normal orientation in the closed chest cavity. This alteration is usually accepted by most investigators as being minimal insofar as the over-all responses studied are concerned. However, when an isolated heart is utilized, the preparation becomes more suspect. Nevertheless, much of the literature contains assumptions and evaluations of both physiologic and pharmacologic responses of the coronary system based on preparations much different than normal. Most of the more quantitative techniques for assaying coronary hemodynamics in situ by necessity require the presence of an anesthetic agent in the blood. This could conceivably be responsible for some alteration in the response patterns of the coronary vasculature. In all fairness it must be pointed out that the objections noted above could just as readily be applied to most vascular systems that are studied.

Sympathetic Nerve Activity and Drug Response

Probably one of the most controversial subjects of study has been the response of

Continued

the coronary vessels to sympathetic nerve activation, and the presence of epinephrine and norepinephrine in the blood perfusing the vessels. In the author's opinion, another problem, namely that of the etiology of shock and its treatment, is very closely allied to the discussion of the functional activity of the coronary vessels. In most discussions of the vascular system and its response to various compounds related to the sympathetic neurohormones, and also to direct nerve stimulation, it is emphasized that the coronary and cerebral vessels are either qualitatively or quantitatively different from the rest of the body vasculature. The renal vasculature, at one time, enjoyed this distinction. First, let us examine the controversy of the differential sympathetic response of the coronary system and, secondarily, relate this to the problem of shock.

If the literature is examined it is at once obvious that not all investigators are of the opinion that the coronary vessels dilate in response to sympathetic nerve activation or to the presence of the catecholamines.[1-8] It should be kept in mind that many investigators utilize the fact that an over-all increase in coronary blood flow is obtained to indicate coronary dilation. It is just as conceivable to find an increase in blood flow per unit time through a constricted vasculature if the perfusing pressure is markedly raised. It has been the authors' experience that it is sometimes difficult to evaluate the response of vascular smooth muscle on the basis of the end result, namely blood-flow increase or decrease.[9-11]

Intra and Extravascular Factors

It is well recognized that a number of physical factors may, in varying degrees under varying conditions, influence the over-all coronary blood flow. The perfusion pressure is certainly of paramount importance.[12] Cross-sectional area of the vascular bed, as regulated by the arterioles, is another important determinant of both degree and direction, i.e., dilation or constriction, of response. The extravascular pressure exerts an influence on many vascular beds but is extremely important in the case of the coronary vessels.[13] This pressure is due primarily to the amount of extracellular and intracellular fluid in the myocardium at any particular time, and also to the basal "tone" of the heart muscle along with the contractile force or pressure exerted during each systolic phase of its activity cycle.

Autoregulation of Coronary Flow

A second regulatory mechanism of the coronary vasculature is the phenomenon of autoregulation. This is not a mechanism limited to the heart, as it apparently occurs in most of the vascular beds of the body. While the actual physical, biochemical, and physiological elements involved in the reaction are still controversial, it appears to be a means by which the relationship between flow and pressure are "sensed" by the very factors which create the phenomenon. The over-all purpose is to deliver the best available level of blood flow to the capillary beds for any given situation. Apparently the metabolic status and the degree of tension on the smooth muscle of the vessel walls are major determinants of this phenomenon.

Metabolic Modification

Intimately related to the concept of autoregulation are the effects of myocardial metabolism and the relation of the oxygen and carbon-dioxide tensions to this metabolic activity. Most studies indicate that hypoxemia induces an increase in coronary blood flow.[14] However, the mechanisms whereby this occurs are still being investigated. Some studies indicate that the effects of an increase in carbon dioxide and lactic acid on coronary blood flow are minimal. Nevertheless, both act on the coronary vasculature in the same manner as they do in other areas of the body, e.g., increase the blood flow.

Many other factors have been studied as to the role they play in the regulation of the blood flow through the coronary system. These include the adenine nucleotides, histamine, calcium and potassium ions, bradykinin, angiotensin, and many others. Most have failed to convince the investigators of their importance in the over-all regulatory scheme.

Arteriolar Activity and Response to Drugs

Certainly the factor that deserves the most consideration in the regulation of coronary blood flow are the peripheral resistance areas of the system, namely, the arterioles. The general consensus among investigators favors the opinion that under most physiological conditions this factor alone determines, in large part, the level of blood perfusing the myocardium. However, it is difficult to give this factor independence. In the author's opinion, it is somewhat analogous to the status of the pituitary gland some years ago. In present-day thinking it is often difficult to determine if this gland is the master or the slave. So it is with the arterioles, as many factors determine the degree of tension to be exerted by the component smooth muscle cells in the vessel walls.

Relationships of Blood Flow and Arteriolar and Drug Response to the Etiology and Treatment of Shock

As was mentioned previously, the relationship betwen the response of coronary vessels to sympathetic nerve stimulation or catecholamine presence in the perfusing blood and the etiology of shock are clouded by marked, and many times emotional, disagreements. Much of the previous history of the rationale for the treatment of the various classes or types of shock is based in large part on the administration of vasopressor (vasoconstrictor) compounds. This approach is based upon the assumption that the primary parameter to be followed and altered is blood pressure. The reasoning is that if the pressure can be raised, the blood flowing through a given tissue will also be increased. Unfortunately, a simple hemodynamic principle was overlooked. That is, if a given procedure raises blood pressure by acting on the smooth muscle of the peripheral resistance vessels (arterioles), these vessels will decrease their caliber and consequently decrease the blood flow through a given tissue or organ.

What is the alternative to the idea that the blood pressure must be raised to combat the syndrome known as shock? The obvious one: increase blood flow to the tissues and organs. As a corollary, we will have to face the fact that the blood pressure may even be allowed to decrease. Thus, it is better to perfuse the tissues with blood at a lowered pressure than to try to force more blood through tightly constricted arteriolar vessels with a high pressure. This then is the rationale in shock therapy for the use of compounds which either block the release of the catecholamines, or their action on the arteriolar smooth muscle, or the use of compounds which are in themselves smooth muscle relaxants.[15,16]

Now when we consider the coronary system, many investigators believe the coronary smooth muscle cells react differently than the rest of the vascular beds of the body. However, as previously mentioned, a small minority, including the author, believe that the evidence is inconclusive, if not altogether incorrect. Certainly the response of the coronary vessels to all other parameters and factors is much the same as the rest of the systemic vasculature. Thus, the coronary response to hypoxemia, various vasodilator and vasoconstrictor drugs (other than epinephrine and norepinephrine), reactive hyperemia, various hormones, etc. are all strikingly analogous to the general vascular response patterns. This latter statement does not mean to imply that we should use teleological reasoning to prove a point, but rather that we should at least consider the possibility, and investigate with open minds, the alternatives.

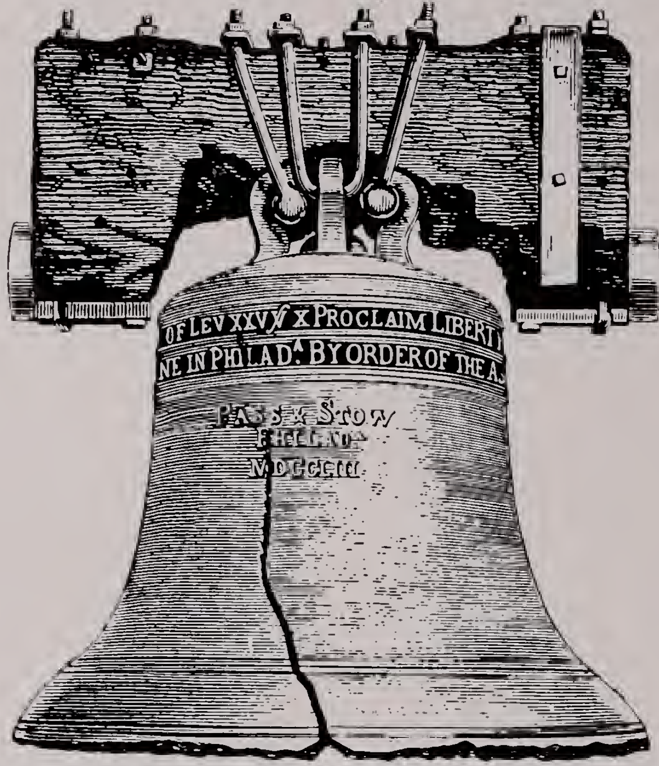
19th CLINICAL CONVENTION OF THE AMA



OF LEV XXV V X PROCLAIM LIBERT
NE IN PHILADA BY ORDER OF THE A
PASS & STOW

PHILADELPHIA, PA.—NOV. 28-DEC. 1, 1965

Plan to attend the world's most comprehensive four-day postgraduate course in recent developments in medical science, and participate in the observance of the founding of the first medical college established in this country—the Medical School of the University of Pennsylvania.

This postgraduate refresher course, conducted by the nation's outstanding medical authorities, will be presented for you in historical Philadelphia. Philadelphia has many luxurious hotels and colorful restaurants. Mail the enclosed registration and room reservations coupons now!

TWO POSTGRADUATE COURSES: Gynecology and Obstetrics; and Cardiovascular Therapeutics (each to be presented in 3 half-day sessions) BREAKFAST ROUNDTABLE DISCUSSIONS: Gynecologic Difficulties in the Adolescent • Early Management of Traffic Accident Patients • Common but Worrisome Pediatric Problems •The Nature of Chronic Bronchitis and Pulmonary Emphysema • Prevention of Long Term Illness: A Practical Approach • Clinical Uses of Electroencephalography SCIENTIFIC SESSIONS: Ulcerative Colitis • Pediatrics • Chemotherapy of Cancer • Preventive Surgery in Cancer • Bacterial Infections • Ultraviolet Irradiation in Medicine • Genetics • Current Status of Drug Therapy in Rheumatology • Psychiatry • Urology • Gastrointestinal Surgery • Cardiovascular Surgery • Current Concepts of Shock • Computers in Medicine • Pain in the Back • Orthopedics • Common Otology Problems • Eye Problems and the Non-Ophthalmologist • CLOSED CIRCUIT COLOR TELEVISION • MOTION PICTURE PREMIERES • Hundreds of SCIENTIFIC AND INDUSTRIAL EXHIBITS

The complete scientific program, plus forms for advance registration and hotel accommodations, will be featured in JAMA October 25

Perinatal Mortality Study

Couvelaire Uterus

Case Report

The 33-year-old mother of this infant was Rh positive and had had four previous Cesarian section deliveries, with all four infants living and healthy. Her physician had planned to do a Cesarian section at 38½ weeks of gestation, but at 37 weeks the mother felt a pressure in the lower abdomen along with an urge to defecate. She fainted in the bathroom. When she regained consciousness, she telephoned and was rushed by ambulance to the hospital, where she continued to complain of increasing pressure and pain in the abdomen. She had had no external bleeding at home, nor was there any evidence in the hospital of external bleeding.

On admission the mother was in shock. Her blood pressure was 70/0, her hemoglobin 7.8 grams%. Her abdomen was very tender, and fetal heart tones were absent. The differential diagnoses included ruptured uterus or abruptio placentae. Couvelaire uterus was also considered. Blood transfusion was promptly started, and the mother was taken to surgery where a laparotomy revealed no tear in the uterus; but a Couvelaire uterus was present, dark blue in color. A low transverse Cesarian section was done, which showed the placenta completely separated with approximately 1000 cc. of clotted blood behind it. A dead infant weighing 5 lbs. 4 oz. was removed along with the entire uterus. The mother received 2000 cc. of blood and left the operating room in good condition.

An autopsy on the infant showed all of the organs to be normal for a stillborn of this size, except for small petechial hemorrhages scattered throughout all of the organs. These petechiae were interpreted to be on the basis of anoxia. Pathologic examination of the uterus showed it to measure 20 x 13 x 6.5 cm. The myometrium thinned, and there was hemorrhage into it.

Comment

Potter states; "A condition described as a Couvelaire uterus is occasionally associated with premature placental detachment. The wall of the uterus, especially in the lateral portions, becomes infiltrated by blood. Hemorrhage is present in muscle bundles, perivascular connective tissue and the subserosa, where it gives the uterus a deep purple color."

The Hennepin County Perinatal Mortality Study Committee presents this case as one that was well handled by the physician, who, presented with a case of sudden shock and abdominal pain in a pregnant woman, started blood promptly and did a laparotomy. It occasionally is necessary to do a hysterectomy with a Couvelaire uterus. The Committee will continue to study perinatal mortality, especially where it is associated with Cesarian section, erythroblastosis, or fetal death during labor.

Robert Koch—Part II*

(1843-1910)

In 1882 Koch announced his discovery of the tubercle bacillus as the cause of tuberculosis. This was a great step forward in the understanding of the disease. Koch states in "The Aetiology of Tuberculosis" concerning the spread of this age-old scourge of mankind, "If the number of victims that a disease claims is the measure of its significance, then all diseases, particularly the most dreadful infectious diseases, such as bubonic plague, Asiatic cholera must rank far behind tuberculosis. Statistics teach that one-seventh of all human beings die of tuberculosis, and that if one considers only the productive middle age group, tuberculosis carries away one-third, and often more, of these." Koch's discovery ranks as one of the most important in the history of medicine. It was of great practical value in the diagnosis and control of the spread of the disease. By now the illustrious old Henle was indeed hailed as a prophet.

In 1890 Koch discovered tuberculin, a boiled glycerine extract from the cultures of tubercle bacilli growing in artificial media. Because of the specific reaction produced when tuberculin is injected into patients with tuberculosis, Koch made the tragic error of concluding that tuberculin was a cure for tuberculosis. Unfortunately many patients came to Berlin with the hopes of being cured. "As a therapeutic agent, tuberculin . . . failed to fulfill the expectation which Koch prematurely raised, but as a diagnostic aid it has proved of immense value."[4] "Tuberculin is of great value in diagnosis both in man and in animals. Thus it has been possible to test cattle and to collect herds of tested cows that are guaranteed to give milk free from all tubercle bacilli. In the United States, public health laws requiring periodical tuberculin tests of dairy herds have to a large extent eliminated the spread of tuberculosis from milk."[5]

Tuberculosis has long ceased to be the first cause of death in this country. Stimulated by Koch's discovery, our National Tuberculosis Association was founded in 1904. Today our state tuberculosis hospitals, state tuberculosis clinics, plus a vigilant year-round survey which includes tuberculin tests in schools and chest x-rays have brought about a steady decline in the disease. Tuberculosis patients who are discovered to have active disease are promptly admitted to one of the state tuberculosis hospitals for intensive treatment and supervision. Because of the effectiveness of modern antituberculosis drugs, the average duration of hospital treatment has been decreased to approximately ten months.

This is a great contrast to the middle of the 19th Century when the immortal musician, Frederic Chopin, was driven to the docks in a wheelbarrow by his indignant neighbors when they discovered he had tuberculosis.

Today many books and pamphlets on tuberculosis along with autographed letters of Robert Koch are part of a tuberculosis collection in the Welch Medical Library at Johns Hopkins.

---

*See Minnesota Med 48:1241, 1965.

Continued

To Koch we owe also the beginnings of modern chemotherapy, important studies in antisepsis, both of which are organically related to the science of immunology. The Nobel Prize was awarded to Koch in 1905.

"Every nation owes an immeasurable debt to the man who gained victories over typhoid and rinderpest and sleeping sickness, uncovered the source of tuberculosis and cholera and Egyptian ophthalmia, and invaded continents, not for the conquest of his fellow-men, but to lead physicians in the warfare against pestilence and plague."[6]

History of Medicine in Wright County*

William B. Young, was listed in Monticello in 1893. He was a graduate of the University of Durham, Newcastle on Tyne, England in 1870. He is no longer listed in Monticello in 1896 and nothing more is known of him. He was not licensed in Minnesota.

Pioneer Dentists

Like many other rural areas in the state, Wright County had no resident dentist for a long time. There were only two before the 1890's — Drs. F. A. Atwater and S. C. Carter - who resided in Delano in 1880 and the early 1880's respectively.

The following list of pioneer dentists who came to Wright County on certain days or perhaps for a week each month makes no claims as to completeness. One of the earliest of these dentists was **Dr. C. Galpin,** who came for very short periods to Monticello around 1868, but may have come there as early as 1865. In 1866 **Dr. Patterson** of St. Paul may have come to Monticello for a week at a time. **Dr. A. L. Bausman,** of the firm Keith and Bausman, Minneapolis, came to Monticello as early as 1867 for a week or so at a time. The newspapers announced that one of the firm would come regularly. He came there at least through 1874.

Dr. J. H. Spalding of Hastings came to Rockford and later to Monticello from 1873 to at least 1876. The newspapers took note of the fact that he did not appear for a few months in 1876 — he had taken a course at the Ohio Dental College of Cincinnati and came home with a degree. He terminated his services to Wright County when he moved to Rochester, Minnesota, in September 1876 to form a partnership with Dr. J. M. Williams.

In 1875 and 76 **Dr. Avery** came to Delano on certain days. At first he saw patients at Young's Hotel and later at the Central House. He stayed in Delano only one or two days at a time. Early in 1879 (first notice appeared February 20, 1879) the **Woodburn Brothers** of Minneapolis announced they would make their services available in Delano the last week of every month. They used part of Dr. Rounsevell's office. For a considerable time it was **W. W. Woodburn** who made the trip to Delano.

In Memoriam

He whom the gods love, dies young. — Menander

NORVIN R. SMITH, M.D.

Dr. Norvin Smith, 52, died July 7th, at his desk at the Hastings State Hospital. Dr. Smith was born in Big Springs, Nebraska, and graduated from the Nebraska College of Medicine in Omaha.

He was a member of the American Medical Association, Hennepin County Medical Society, and the Minnesota State Medical Association.

He is survived by his wife, a son and a daughter.

FRED Z. HAVENS, M.D.

Dr. Fred Havens, 85, a member of the Section of Plastic Surgery of the Mayo Clinic and emeritus professor of plastic surgery in the Mayo Graduate School of Medicine, died June 29, of coronary thrombosis. He was born in Hallville, Illinois, and graduated from the Rush Medical College of the University of Chicago.

Dr. Havens was certified as a specialist in otolaryngology and plastic surgery by the American Board of Otolaryngology and was a member of the American Academy of Ophthalmology and Otolaryngology, American Association of Oral and Plastic Surgery, American Laryngological, Rhinological and Otological Society, American Medical Association, American Laryngological Association, American Society of Plastic and Reconstructive Surgery, Minnesota Academy of Ophthalmology and Otolaryngology, Zumbro Valley Medical Society, Alumni Association of the Mayo Graduate School of Medicine, and a 50 Club and associate member of the Minnesota State Medical Association.

He is survived by a daughter and a son, Dr. Fred Z. Havens, Jr. of Riverside, California.

FREDERICK W. HOFFBAUER, M.D.

Dr. Frederick W. Hoffbauer, 64, chief of medicine at Hennepin County General Hospital, died of a heart attack July 30th. He was born in St. Paul and graduated from the University of Minnesota Medical School.

Dr. Hoffbauer was a professor of medicine in the University of Minnesota College of Medical Science. He was a member of the American Medical Association, Minnesota State Medical Association and Hennepin County Medical Association. Dr. Hoffbauer was a member of the Board of Editors of MINNESOTA MEDICINE.

He is survived by his wife.

WILLIAM R. BAGLEY, M.D.

Dr. William R. Bagley, 95, pioneer Duluth physician, died July 28th. He was born in St. Charles, Illinois, and graduated from the University of Michigan Medical School.

Dr. Bagley was one of the organizers of the Duluth Chapter of the Izaak Walton League and was president of the state society in 1934. Later he became a national director of the league. In 1940 he was chosen the 17th member of the Duluth Hall of Fame largely because of his community leadership.

He was a member of the American Medical Association and the St. Louis County Medical Society and a life and 50 Club member of the Minnesota State Medical Association. Dr. Bagley was a fellow of the American College of Surgeons.

He is survived by his wife, two sons and four daughters. Doctors Charles and Elizabeth Bagley of Duluth are among his survivors.

LEWIS S. JORDAN, M.D.

Dr. Lewis S. Jordan, 69, of Granite Falls, a past president of the Minnesota Tuberculosis and Health Association died July 17th. He was supervisor of the Riverside Tuberculosis Sanitarium in Granite Falls until its closing in 1963, and since then has been director of the Riverside out-patient department.

He was born in Alfred, New York, and graduated from the Eclectic Medical College in Cincinnati. He was a member of the American Medical Association, Camp Release District Medical Society and the Minnesota State Medical Association.

He is survived by his wife, Dr. Kathleen Jordan.

DAVID B. PETERSON, M.D.

Dr. David B. Peterson, 64, St. Paul physician, died suddenly July 21st. A graduate of the University of

Continued

Minnesota Medical School, Dr. Peterson had practiced medicine in St. Paul for thirty-five years. He was born in St. Paul and was a member of the staffs of St. John's and Bethesda Hospitals.

He was a member of the American Medical Association, Ramsey County Medical Society and the Minnesota State Medical Association.

He is survived by his two sisters.

MYRON LYSNE, M.D.

Dr. Myron Lysne, 60, Minneapolis physician, died August 15th, while boating near Fort Frances, Ontario. He was alone in his 14-foot skiff when he suffered a heart attack.

Dr. Lysne was born in Northfield and was a graduate of the University of Minnesota Medical School. He was a staff member at Fairview and North Memorial Hospitals, and a member of the Hennepin County Medical Society, Minnesota State Medical Association and American Medical Association.

He is survived by his wife, a son and a daughter.

MARIE A. MOQUIN, M.D.

Dr. Marie A. Moquin, 85, St. Paul physician, died June 26th. She was born in Oakland, California, and secured her medical degree from the Wisconsin College of Physicians and Surgeons.

Dr. Moquin was a member of the American Medical Association, Ramsey County Medical Society, and an associate member of the Minnesota State Medical Association.

JULIUS C. BUSCHER, M.D.

Dr. Julius C. Buscher, 74, St. Cloud physician, died August 8th. He was born in Osnabrueck, Germany, and obtained his medical degree at the University of Heidelberg-Kiel.

He was a member of the American Medical Association and Stearns-Benton Medical Society, and an associate member of the Minnesota State Medical Association. Dr. Buscher was the author of the book "The Doctor's Last Message."

He is survived by his wife and son.

MELVYN E. WITTHAUS, M.D.

Dr. Melvyn E. Witthaus, 38, White Bear Lake physician, drowned August 29th, when his sailboat capsized during a race on White Bear Lake. He was born in Kansas City, Missouri, and had been a resident in the St. Paul area about seventeen years. He was a graduate of Harding High School and the University of Minnesota Medical School.

Dr. Witthaus was a member of the American Medical Association, Minnesota State Medical Association and the Ramsey County Medical Society.

He is survived by his wife, two daughters and two sons.

JOHN A. MALMSTROM, M.D.

Dr. John A. Malmstrom, 63, East Range physician, died August 21st, 1965. He was born in Chisholm, Minnesota, and graduated from the University of Minnesota Medical School.

Dr. Malmstrom was a member of the American Medical Association, Range Medical Society and the Minnesota State Medical Association.

He is survived by his wife and two children.

ROBERT R. REMSBERG, M.D.

Dr. Robert R. Remsberg, 52, Tracy physician, died of a heart attack in his office, August 30th. He was born in Iola, Kansas, and received his medical degree at the University of Kansas.

Dr. Remsberg was a three-term member of Tracy's school board, the city's health officer since 1948, and was a Lyon County deputy coroner. He was a member of the American Medical Association, Lyon-Lincoln Medical Society and the Minnesota State Medical Association.

He is survived by his wife, two sons, and a daughter.

ARCHIBALD W. GRAHAM, M.D.

Dr. A. W. Graham, 87, Chisholm physician, died August 25, following a lingering illness. He was born in Fayetteville, North Carolina, and obtained his medical degree at the University of North Carolina and the University of Maryland. It was while Doctor Graham was in medical school that he gained notable reputation as a ball player. During the summers of 1905 and 1906 he played on the New York Giants' team as outfielder.

He came to Chisholm in 1909 and practiced there until his retirement. He was very active in many community projects, was a member of Kiwanis and the Masons, a member of the school board, a 50-club and associate member of the Minnesota State Medical Association, a member of the Range County Medical Society and the American Medical Association.

He is survived by his wife.

He that studies to know duty, and labors in all things to do it, will have two heavens — one of joy, peace and comfort on earth, and the other of glory and happiness beyond the grave. — Bowring

No-Load Funds Versus Load Funds

A great deal of discussion and writing has been done on this subject in the past. With a few "no-load" funds starting to appear among the list of best performing investment funds, this load factor will require even more critical evaluation in the future.

In order to intelligently evaluate this "load" question, it is necessary to consider three basic loads or costs in connection with the acquisition, retention and disposition of investment fund shares.

(1) Acquisition Cost — "Front Load"

The majority of funds levy a charge for acquisition of their shares. This charge averages about 8% of net asset value. The funds that levy this charge do not usually charge a redemption fee upon disposition of their shares.

(2) Management Fee — "Middle Load"

This is the fee that a fund pays the managing company. It is an annual fee based upon a percentage of asset value ranging all the way from ¼% to 1½%. This management cost varies so widely that over a ten-year period, many "load" funds collect less fees (including acquisition charges) than the so-called "no-load" funds.

(3) Redemption Fee — "End Load"

This fee is almost standard among the "no loads," but very few "load" funds make a charge for redemption of shares. The most common charge is 1% of net asset value — a sizeable fee on a fund which has increased substantially in value over a period of years. The levying of this fee as a partial substitute for front load or acquisition charge tends to artificially improve the performance results of the "no loads."

If you combine all three of these "load" factors for a ten-year period, many of the so-called "no-load" funds are more costly to own than a "load" fund. To illustrate this principle, we have studied Massachusetts Investors Growth Stock Fund, a "load" fund, and DeVegh Mutual Fund, a "no-load" fund. We have assumed an initial investment of $10,000 on January 1, 1954, reinvestment of all distributions and liquidation of the shares on December 31, 1963.

The investment in Massachusetts Investors Growth Stock Fund incurred an $850 load upon acquisition and $633 management fees over the ten-year period for a total of $1,483, or 14.8% of the initial investment. The fund shares had a value of $41,836 on December 31, 1963, which would be the net liquidation value since there is no redemption fee for sale of shares.

The investment in DeVegh Mutual Fund was made without load charge, the ten-year management fee was about $1,380, and since DeVegh charges a redemption fee of 1% of net asset value, the redemption fee would be $415. Total fees on this "no-load" investment were 17.95% of the initial investment. The fund had a total value of $41,488 on December 31, 1963, less the $415 redemption fee, or a net value of $41,073.

This brief comparison illustrates the fallacy in looking at load or acquisition cost as a determining factor in choosing an investment fund. In this particular case, the total fees over the ten-year period of ownership were 3% higher on the "no-load" fund than they were on the fund charging 8½%.

It also illustrates the fallacy of choosing a fund even on the basis of total fees charged. On the basis of acquisition fee, you would choose DeVegh. On the basis of total fees, you would choose Massachusetts Investors Growth Stock Fund. This does not mean that DeVegh is an illogical commitment; on the basis of *net investment results*, it is still superior to 90% of the funds sold today. To eliminate it from consideration because of high over-all fees would be a mistake — just as the elimination of Massachusetts Investors Growth Stock Fund on the basis of its 8½% acquisition cost would be in very bad judgment.

We have maintained for years that "net investment result" is the only valid basis for the choice of funds. This comparison is just another means of strengthening this premise and illustrating the general irrelevance of fees charged. In choosing a fund, the amount invested and the net liquidation value of the shares at any given time are the most significant factors. In the event of equal investment quality of two funds, fees charged would be of possible significance — but even then total fees should be considered, not just the acquisition cost of the shares.

Early Specialization

The art of Medicine in Egypt is thus exercised: one physician is confined to the study and management of one disease; there are of course a great number who practice this art; some attend to the disorders of the eyes, others to those of the head, some take care of the teeth, others are conversant with all the diseases of the bowels; whilst many attend to the cure of maladies which are less conspicuous. — Herodotus (484-424 B.C.)

What is the single most important contribution to drug research?

It was made 175 years ago

when President Washington signed the first U.S. patent law. For patents mean drug progress. For example, of the 604 important drugs introduced worldwide since 1941, the majority originated in the U.S. drug industry. By contrast, a major west European nation, which has no patent protection, contributed one.

How great is the contribution of drug patents? The answer is told in life itself: our children live 10 years longer than we, and need not suffer polio, measles, diphtheria, tuberculosis, rheumatic heart disease, and a dozen other illnesses we grew up fearing. We can expect these benefits to multiply—as long as our patent system remains strong.

Bush Leadership Fellows Program announced opening of competition for its 1965-66 awards, which will select four Minnesotans for 16 to 24 month fellowships. Sponsor of the program is The Bush Foundation of St. Paul. Deadline for receipt of applications is November 1, 1965. Applications can be obtained from David Roberts, W-3071 First National Bank Building, St. Paul.

Star-spangled money saver

Used properly, this red, white and blue writing "tool" can take care of your money-saving problems in a single stroke.

You just grasp it firmly and put your John Hancock on an application for the Payroll Savings Plan where you work.

This authorizes your employer to make your savings automatic. He sets aside a small amount from your check each payday toward the purchase of U. S. Savings Bonds.

The amount can be any size. The important thing is it's saved regularly.

Don't worry if you have to use an ordinary pen instead of a star-spangled one. You'll get a nice star-spangled feeling to make up for it.

Quicks facts about Series E Savings Bonds

- ✓ You get back $4 for every $3 at maturity
- ✓ You can get your money when you need it
- ✓ You pay no state or local income tax on the interest and can defer federal tax until you cash the Bond.
- ✓ Your Bonds are replaced free if lost, destroyed or stolen

The Blue Shield

Blue Shield Celebrates Its 25th Anniversary

This year marks the 25th anniversary of the founding of the first Blue Shield type plan in 1939 by the California Medical Association.

The fledgling California infant in 1939 was the first step in a phenomenal quarter century of growth. Starting with the California plan, followed later in 1939 by a Blue Shield plan in Michigan, Blue Shield has grown to where it now comprises a network of 83 independent plans in the United States, Canada, and Jamaica, coordinated by the National Association of Blue Shield Plans in Chicago.

From barely 12 million subscribers in 1949, 10 years after its inception, membership in the succeeding 15 years has soared to over 53 million. Benefits paid to a record 53,450,349 Blue Shield subscribers in 1963 topped the billion dollar mark for the first time.

What are the reasons for such an outstanding growth record?

Coming out of the depression in the late '30s, Americans felt the need for a vehicle which would enable them to prepay their medical expenses. The financial ravages of the depression were disastrous to those who incurred heavy medical expenses.

The government was ready with a compulsory health insurance program when Blue Shield and other voluntary health care prepayment plans were made available to the people. Americans, given the opportunity to choose between government and voluntary health care, voted with their dollars for the voluntary approach in overwhelming numbers.

Today, more than 77 per cent of the United States population has some form of a voluntary health-care prepayment plan. Blue Shield covers 26.41 per cent of the United States population, handling 46 per cent of the medical and 36 per cent of the surgical coverage in this country.

The main reason for this widespread acceptance of Blue Shield is that benefits have kept pace with the medical-surgical needs of members.

Blue Shield strives to give subscribers "payment-in-full" for their medical-surgical expenses . . . and these payments are accepted as full payment by over 125,000 U. S. physicians.

Blue Shield has discovered that it can now extend benefits that it once thought impossible. Primarily, this is due to the unique relationship that Blue Shield has with both doctor and patient . . . and the nonprofit character of the organization.

At first, many Blue Shield plans limited coverage to inhospital surgical cases. A few included obstetrical cases and fewer offered limited coverage for nonsurgical cases. Almost all plans excluded coverage for diagnostic services.

Today, Blue Shield plans generally offer surgery in or out of the hospital, without limitation to the number of procedures; obstetrical services in or out of the hospital, including normal care of the newborn; and medical services in the hospital to 120 days or more.

Also usually offered is general anesthesia service in or out of the hospital by a physician anesthesiologist not employed by the hospital; diagnostic or therapeutic X rays; and professional laboratory interpretations in or out of the hospital.

Blue Shield, upon attaining the quarter century mark, has not paused to rest on its considerable laurels. It is moving ahead to new horizons of broader coverage for more people.

Classified

Classified advertising rates are twenty (20) cents a word; minimum monthly charge $5.00; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of MINNESOTA MEDICINE, *496 Lowry Medical Arts Bldg., St. Paul, Minn. 55102*

SHARE SPACE AT SOUTHDALE? It might be the answer for you. Especially with new Fairview Hospital opening in October right next door. Medical specialist will share equipped and staffed suite. Contact: MINNESOTA MEDICINE — 325; 496 Lowry Medical Arts Building, St. Paul 55102.

BADLY NEEDED — G.P., Internist or Surgeon to associate with two-man G.P. partnership. Unapposed territory. New hospital, nursing home, children's home! Superb hunting, fishing, golf, pool, winter arena. Progressive town! Delmore Clinic, Roseau, Minnesota 56751.

A 13 MEMBER specialty group in the Midwest will need several men to replace and add to present staff. This has been a rewarding group for years, is now, and will be for years to come. We need 3 internists, 1 dermatologist, 1 ob-gyn, 1 pediatrician, 1 general and thoracic surgeon, 1 orthopedist, 1 ophthalmologist, 1 otorhinolaryngologist, and 1 psychiatrist. This is a very good town for a family man. Three colleges (1 a State College). Good schools and excellent recreation programs. Good hunting, fishing and water sports. Applicants should be board certified or completing requirements. Write MINNESOTA MEDICINE — 324; 496 Lowry Medical Arts Building, St. Paul 55102.

WANTED PEDIATRICIANS AND INTERNISTS. Office space now available in new, modern, well established center — excellent opportunity for good earnings and professional pursuits — fastest growing suburban area. Write or phone A. G. Erickson, 7033 Edgewood Avenue North, Minneapolis Tel 533-7332.

WANTED: Board Certified or eligible internist to associate with group in large, active practice in Minneapolis. Group consists of Surgeon, Obstetrician, Pediatrician and Internist maintaining downtown and suburban offices. Partnership in mind. Contact: Jesse J. Barron, M.D., 1127 Medical Arts Building, Minneapolis, Minnesota 55402, FEderal 2-8259."

FOR RENT: Successful medical building. Opportunity for doctor to start new group. Rent at less than $3.00 square foot. Deluxe, modern, air-conditioned, all brick building with capacity up to four doctors. Located at 36th Avenue North and Noble Avenue in Northwest Suburban Minneapolis. For further information: Call Noble Drug at 588-9449 and ask for Ben or Lou.

MORGAN, MINNESOTA, Wants General Practitioner — present physician retiring after 33 years. Opportunity to take over well established practice. Progressive community in the best rural area of Southern Minnesota. Office space and equipment available. Call or write John Hageman, Pharmacist, Morgan, Minnesota. Telephone Morgan No. 96.

WHITE BEAR LAKE, MINNESOTA. A suburban community of 35,000 and growing fast. Available several ground floor air-conditioned suites in fireproof building in central business district, free municipal parking lot at second entrance in rear. See: N. R. Dittberner, 316 Washington Avenue, White Bear Lake. Telephone: Collect anytime 429-7787.

BUSY, GROWING aggressive 3-man partnership in Northwest Wisconsin serving a trade area of 15,000 needs a well-trained recent graduate with fulfilled military obligations to associate immediately on excellent salary, with partnership in 1 year if mutually agreeable. Modern 15 room air conditioned brick clinic building is being doubled in size this year. 32 bed hospital and new 42 bed nursing home one minute from clinic. New 1500 student consolidated school. Excellent hunting, fishing and outdoor sport facilities in immediate area. Contact: MINNESOTA MEDICINE — 317; 496 Lowry Medical Arts Building, St. Paul 55102.
